Abstract
Abdominal obesity is a strong predictor of metabolic disorders. Prospective data on the association between the Mediterranean diet and surrogate markers of abdominal adiposity are scarce. The present study evaluated the relationship between adherence to the Mediterranean diet and (1) changes in waist circumference (WC) and (2) 10-year incidence of abdominal obesity. We conducted a prospective, population-based study in 3058 male and female Spaniards aged 25–74 years, followed from 2000 to 2009. Dietary intake and leisure-time physical activity levels were recorded using validated questionnaires. Weight, height and WC were measured. Adherence to the Mediterranean diet, determined using the previously validated REGICOR-Mediterranean diet score (R-MDS), based on the distribution of population food intake and on the dietary recommendations (MDS-rec), was negatively associated with WC gain (P=0.007 and 0.024, respectively) in fully adjusted models. In the multivariate logistic analysis, the odds of abdominal obesity incidence decreased across the tertiles of the R-MDS, but the association was not significant. In conclusion, adherence to the Mediterranean diet was associated with lower abdominal fat gain, but not with 10-year incidence of abdominal obesity.

Key words: Abdominal obesity: Mediterranean diet: Waist circumference

Abdominal obesity is a strong predictor of metabolic disorders and premature mortality(1,2). Therefore, increasing secular trends of abdominal obesity in recent decades(3) and the recently reported high prevalence of abdominal obesity(3,4) are a matter of health policy concern.

Sedentary lifestyle and dietary patterns promoting energy overconsumption are considered to be the main drivers of the obesity epidemic(5). Epidemiological evidence indicates an inverse association between adherence to the Mediterranean diet and general obesity(6,7). However, little is known about the impact of this dietary pattern, which includes foods characteristic of the Mediterranean olive grove areas, on abdominal fat accumulation(8). An inverse association has been found in some(9) but not in all(10) cross-sectional studies, and long-term prospective data are lacking.

Most studies have measured adherence to the Mediterranean diet by scores based on consumption patterns and modified to reflect the particular study population(11). A Mediterranean diet score has also been created a priori by a few studies(12), using food intake recommendations.

The present study had three objectives: (1) to explore the prospective association of adherence to the Mediterranean diet with waist circumference (WC) changes; (2) to determine the 10-year incidence of abdominal obesity defined by WC cut-offs, according to adherence to the Mediterranean diet in

Abbreviations: MDS-rec, Mediterranean diet score based on the dietary recommendations; R-MDS, REGICOR-Mediterranean diet score based on the distribution of population food intake; LTPA, leisure-time physical activity; WC, waist circumference.

Materials and methods

Study population

Data were obtained from a population-based survey conducted in Girona (Spain) in 2000 and 2009. The baseline survey carried out in 2000 examined a randomly selected, population-based sample of 3085 men and women aged 25–74 years (participation rate: 71·0%). A two-stage sampling method was used in 2000: seventeen towns were randomly selected in the first stage. Half of the towns were urban (>10 000 inhabitants) and half were rural (500–10 000 inhabitants). The second sampling stage consisted of randomly recruiting the same number of female and male participants, stratifying by 10-year age groups from the closest census.

In 2009, the 2715 non-institutionalised participants still residing in the catchment area were invited for re-examination, and 2181 attended (follow-up participation rate: 80·3%). Participants following a special diet at re-examination (n 207 (9·8%)) were excluded. The participants were duly informed, and they signed their consent to participate in the study. The project was approved by the local Ethics Committee (CEIC-PSMAR, Barcelona, Spain).

Anthropometrics

A calibrated precision scale was used for measuring weight. Readings were rounded up to 200 g. Height was measured in the standing position and rounded up to the nearest 0·5 cm. Weight was divided by height squared (kg/m²) to establish the BMI.

WC was measured midway between the lowest rib and the iliac crest in the horizontal position. Readings were rounded up to the nearest 0·5 cm. Abdominal obesity was defined by sex-specific cut-offs of more than 102 cm for men and more than 88 cm for women(13).

All the anthropometric parameters were measured both at baseline and at follow-up, using the same protocol.

Dietary intake assessment

Dietary intake was determined using a validated(14,15) FFQ, administered by a trained interviewer at baseline and at follow-up. In a 166-item food list including alcoholic and non-alcoholic beverages, the participants indicated their usual consumption frequency and chose from ten frequency categories ranging from never or less than once per month to six or more times per d.

Adherence to the Mediterranean diet was determined by the validated REGICOR-Mediterranean diet score (R-MDS)(14). The published Pearson correlation for the energy-adjusted R-MDS multiple recalls was 0·48 (13). The R-MDS was calculated using two strategies: sex-specific tertile distribution of food intake(14) (R-MDS) and dietary recommendations established in Spain(16,17) (MDS-rec). The lowest tertile was coded as 1, medium as 2 and the highest as 3 for cereals, fruits, vegetables, legumes, fish, olive oil and nuts. For meat (including red meat, poultry and sausages) and dairy products, the score was inverted, with the highest tertile being coded as 1 and the lowest as 3. Moderate red wine consumption (up to 20 g/d) was coded as 3, and that more or less than this daily portion was coded as 1. Using the second strategy, consumption that met the recommendations for cereals, fruits, vegetables, legumes, fish, olive oil, nuts and dairy products was coded as 3, that at least weekly as 2 and that less than weekly levels as 1 for legumes, fish and nuts; consumption at least daily was coded as 2 and that less than daily levels as 1 for cereals, fruits, vegetables, olive oil and dairy products (see Supplementary Appendix 2, available online). For meat (including red meat, poultry and sausages) and dairy products, the score was partially inverted, with consumption more than weekly levels being coded as 1, that weekly as 2 and that meeting the recommended levels as 3. Red wine consumption was coded as described previously.

Energy misreporting

Implausible energy reporters were identified by the revised Goldberg method described previously(18). BMR was calculated using the Mifflin equation(19):

\[
BMR = \text{weight}_{\text{kg}} \times 9·99 + \text{height}_{\text{cm}} \times 6·25 - (\text{age}_{\text{y}} \times 4·92) + 5 \cdot \text{among men},
\]

\[
BMR = \text{weight}_{\text{kg}} \times 9·99 + \text{height}_{\text{cm}} \times 6·25 - (\text{age}_{\text{y}} \times 4·92) + 161 \cdot \text{among women}.
\]

The index of variability (S) in the components of energy balance was determined. Subjects with BMR falling above or below the upper and lower 95% CI limits of 1·96 standard deviations for plausible energy intake were characterised as implausible energy reporters.

The following formula was used:

\[
\text{Cut-off} = \text{PAL} \times \exp \left[ \pm 1·96 \times \frac{S}{\sqrt{n}} \right],
\]

where

\[
S = \sqrt{\frac{C_{\text{wEI}}}{d} + \frac{C_{\text{wBMR}}^2}{d} + \frac{C_{\text{d}}^2}{d}},
\]

where \(d\) is the number of recording days; \(C_{\text{wEI}}\) and \(C_{\text{wBMR}}^2\) represent the intra-individual variations in the repeated measures of energy intake and BMR, respectively; and \(C_{\text{d}}^2\) represents the inter-individual variation in physical activity levels (PAL)(20).

Other variables

The validated Minnesota leisure-time physical activity (LTPA) questionnaire was administered by a trained interviewer(21,22). LTPA is expressed as metabolic equivalents £ min/d.
The measurements of smoking habits and demographic and socio-economic variables were obtained from structured standard questionnaires administered by trained personnel. The participants were dichotomously categorised into non-smokers (never smokers and ex-smokers with more than 1 year of smoking cessation) and current smokers. Maximum educational level attained was determined and dichotomously recorded for analysis as primary school v. secondary school or university.

All dietary and energy intake and expenditure measurements were performed both at baseline and at follow-up, using the same protocol.

**Statistical analysis**

General linear modelling procedures were used to compare the baseline characteristics of the participants by tertiles of the R-MDS and by categories of the MDS-rec. ANOVA test and polynomial contrasts were used to determine overall $P$ and $P$ for linear trend, respectively, for normally distributed continuous variables. The Kruskal–Wallis test was used to determine overall $P$ for non-normal distribution. Overall $P$ and $P$ for linear trend for categorical variables were obtained using the Pearson $\chi^2$ and Mantel–Haenszel linear-by-linear association $\chi^2$ tests, respectively.

Linear regression models were fitted to analyse the association between changes in WC and adherence to the Mediterranean diet at baseline. Changes in WC (in cm; continuous variable) were included as the dependent variable and scores as explanatory variables. For analyses, three models were fitted. The first model included sex (men/women; dichotomous), age (years; continuous) and baseline WC. The second model included smoking (yes/no; dichotomous), energy intake (kcal; continuous), alcohol consumption (g; continuous), educational level (more than primary school yes/no; dichotomous), LTPA (metabolic equivalents x min/d; continuous), and energy under- and over-reporting (both yes/no; dichotomous). The third model included changes in BMI (BMI at follow-up – BMI at baseline; continuous) to determine whether changes in WC are independent of changes in BMI. This model was adjusted by sex (men/women; dichotomous), age (years; continuous), smoking (yes/no; dichotomous), energy intake (kcal; continuous), alcohol consumption (g; continuous), educational level (more than primary school yes/no; dichotomous), LTPA (metabolic equivalents x min/d; continuous), and energy under- and over-reporting (both yes/no; dichotomous). The model was adjusted by sex (men/women; dichotomous), age (years; continuous), smoking (yes/no; dichotomous), energy intake (kcal; continuous), alcohol consumption (g; continuous), educational level (more than primary school yes/no; dichotomous), LTPA (metabolic equivalents x min/d; continuous), and energy under- and over-reporting (both yes/no; dichotomous). The model was adjusted by sex (men/women; dichotomous), age (years; continuous), smoking (yes/no; dichotomous), energy intake (kcal; continuous), alcohol consumption (g; continuous), educational level (more than primary school yes/no; dichotomous), LTPA (metabolic equivalents x min/d; continuous), and energy under- and over-reporting (both yes/no; dichotomous).

under- and over-reporting (both yes/no; dichotomous). Participants with baseline abdominal obesity were excluded from analysis in multiple logistic regression models assessing the association between R-MDS and MDS-rec adherence at baseline and 10-year incidence of abdominal obesity. Baseline R-MDS and MDS-rec values are represented by tertiles and categories, respectively.

To explore effect modification according to sex, R-MDS and MDS-rec, we modelled interaction terms for sex/R-MDS and sex/MDS-rec. Differences were considered significant if \( P < 0.05 \). Statistical analysis was carried out using SPSS version 18.0. (SPSS, Inc.).

**Results**

The prevalence of abdominal obesity at baseline was 29.3% (men: 23.8%; women: 34.4%) and at follow-up was 40.8% (men: 30.5%; women: 50.5%). Of the 1329 participants without abdominal obesity at baseline, 291 (21.9%) had abdominal obesity at follow-up (men: 14.9%; women: 29.6%).

Participants with high adherence to the Mediterranean diet were less prone to smoke and had a lower prevalence of abdominal obesity at follow-up (men: 14.9%; women: 29.6%).

The prevalence of abdominal obesity at baseline was 29.3% (men: 23.8%; women: 34.4%) and at follow-up was 40.8% (men: 30.5%; women: 50.5%). Of the 1329 participants without abdominal obesity at baseline, 291 (21.9%) had abdominal obesity at follow-up (men: 14.9%; women: 29.6%).

**Discussion**

In the present prospective study, it was found that high adherence to the Mediterranean diet was associated with a

*A. N. Funtikova et al.*
The association between WC and cardiometabolic risk(2).

This is a cause of concern due to the direct abdominal obesity at baseline. Most importantly, 10-year study, general obesity was about 7% less prevalent than which might be due to differences in the surrogate markers increase in dietary scores was associated with a 1.7 cm abdominal adiposity gain. In the present study, a 10-point a protective association of the Mediterranean diet with syndrome and its components has revealed a positive effect adherence to the Mediterranean diet on the metabolic terranean diet and WC changes. In the SUN prospective surveys(11,25,26) evaluated the association between the Medi- lower gain in abdominal adiposity but not with the incidence of abdominal obesity within 10 years. In recent decades, increased WC has been reported for several populations(3). In the present study, general obesity was about 7% less prevalent than abdominal obesity at baseline. Most importantly, 10-year incidence of abdominal obesity was 14.8% higher than that of general obesity. This is a cause of concern due to the direct association between WC and cardiometabolic risk(2).

A recently published meta-analysis(23) of the impact of adherence to the Mediterranean diet on the metabolic syndrome and its components has revealed a positive effect on WC changes in eleven randomised controlled trials. It is worth noting that this was mainly due to one trial that demonstrated a mean WC difference of −4.20 cm (−7.99 to −0.41) between the Mediterranean and control diets(24).

Among the prospective observational studies, only three surveys(23,27,28) evaluated the association between the Mediterranean diet and WC changes. In the SUN prospective cohort (Seguimiento Universidad de Navarra; University of Navarra follow-up) the difference in WC between the highest and lowest tertiles of the Mediterranean diet score in sex- and age-adjusted models was almost 0.1(26). Participants in the Framingham Heart Study Offspring Cohort who closely adhered to the Mediterranean diet had a significantly lower WC than their low-adhering peers(25). Additionally, the Supplementation en Vitamines et Minéraux Antioxydants (SU.VI.MAX) study reported a negative association between WC gain and two of the three Mediterranean diet score indices calculated(24).

Our data confirm the findings of previous studies showing a protective association of the Mediterranean diet with abdominal adiposity gain. In the present study, a 10-point increase in dietary scores was associated with a 1.7 cm decrease in WC.

Cross-sectional studies(23,27) have reported mixed results, which might be due to differences in the surrogate markers of abdominal obesity used (WC, waist:hip ratio and waist: height ratio). In the present study, cross-sectional analysis revealed that the risk of abdominal obesity decreased with high adherence to the Mediterranean diet.

Some(16,28,29) but not all(30,31) prospective studies provide evidence for the protective effects of the Mediterranean diet on the incidence of general obesity. To our knowledge, no previous study has addressed the association between the Mediterranean diet and incidence of abdominal obesity. We observed an inverse, but non-significant, association between adherence to the Mediterranean diet and incidence of abdominal obesity. One explanation for these results is the moderate magnitude of the association of WC change with the R-MDS. On the other hand, a substantial increase in the prevalence of abdominal obesity at follow-up and low mean change in the R-MDS (−0.5 points) during 10 years cancelled the effect of the Mediterranean diet on the incidence of abdominal obesity. This outcome is of interest at the public health level because it is also important to know which diets do not promote abdominal obesity.

Higher adherence to the Mediterranean diet was associated with high consumption of MUFA and PUFA, high dietary fibre intake and low energy density (data not shown). High consumption of fibre might partially explain the impact of the Mediterranean diet on abdominal adiposity through various protective mechanisms, with the increase of satiety and decrease of energy consumption(32,33), modification of hepatic cholesterol metabolism(30), and increased production of SCFA being among them(34). Du et al.(35) found that a 1 kcal/g (4kJ/g) increase in energy density was associated with a 0.09 cm gain in WC per year. It has been hypothesised that energy density could be a mediator between depressive symptoms and abdominal adiposity gain(36). However, the

* Model 1 includes sex (men/women; dichotomous), age (years; continuous) and baseline WC (cm; continuous).
‡ Model 2 additionally includes smoking (yes/no; dichotomous), energy intake (kcal; continuous), alcohol consumption (g; continuous), educational level (more than primary school yes/no; dichotomous), leisure-time physical activity (metabolic equivalents × min/d; continuous), and energy under- and over-reporting (both yes/no; dichotomous).
‡ Model 3 includes variables of model 2 and changes in BMI (BMI at follow-up – BMI at baseline; continuous).

Our data confirm the findings of previous studies showing a protective association of the Mediterranean diet with abdominal adiposity gain. In the present study, a 10-point increase in dietary scores was associated with a 1.7 cm decrease in WC.

Cross-sectional studies(23,27) have reported mixed results, which might be due to differences in the surrogate markers of abdominal obesity used (WC, waist:hip ratio and waist: height ratio). In the present study, cross-sectional analysis revealed that the risk of abdominal obesity decreased with high adherence to the Mediterranean diet.

Some(16,28,29) but not all(30,31) prospective studies provide evidence for the protective effects of the Mediterranean diet on the incidence of general obesity. To our knowledge, no previous study has addressed the association between the Mediterranean diet and incidence of abdominal obesity. We observed an inverse, but non-significant, association between adherence to the Mediterranean diet and incidence of abdominal obesity. One explanation for these results is the moderate magnitude of the association of WC change with the R-MDS. On the other hand, a substantial increase in the prevalence of abdominal obesity at follow-up and low mean change in the R-MDS (−0.5 points) during 10 years cancelled the effect of the Mediterranean diet on the incidence of abdominal obesity. This outcome is of interest at the public health level because it is also important to know which diets do not promote abdominal obesity.

Higher adherence to the Mediterranean diet was associated with high consumption of MUFA and PUFA, high dietary fibre intake and low energy density (data not shown). High consumption of fibre might partially explain the impact of the Mediterranean diet on abdominal adiposity through various protective mechanisms, with the increase of satiety and decrease of energy consumption(32,33), modification of hepatic cholesterol metabolism(30), and increased production of SCFA being among them(34). Du et al.(35) found that a 1 kcal/g (4kJ/g) increase in energy density was associated with a 0.09 cm gain in WC per year. It has been hypothesised that energy density could be a mediator between depressive symptoms and abdominal adiposity gain(36). However, the
mechanisms linking WC changes and energy density are not understood. Fatty acids can activate the PPARy gene\cite{37}, which is involved in lipid metabolism and particularly in the process of adipocyte differentiation. It has been demonstrated that the WC gain caused by the 12Ala allele carriers of the PPARy gene was depressed by adherence to the Mediterranean diet\cite{38}.

Assessing the adherence to the Mediterranean diet by a score based on population-based food consumption distribution is specific to a particular population, making it difficult to compare results between studies. This construct has mainly been used by studies reporting on the association between adherence to the Mediterranean diet and incidence of obesity and/or changes in anthropometric markers of adiposity\cite{11,27}.

To overcome the limitation on comparability of results, we calculated two scores, one based on food distribution and the other based on food intake recommendations. We observed no meaningful impact of the type of construct used on the association between the score obtained and WC or incidence of abdominal obesity.

The strengths of the present study are the population-based design, the high participation rate during follow-up, and the measurement of anthropometric variables at baseline and at 10-year follow-up. Furthermore, dietary intake and LTPA data were recorded using validated questionnaires and all the analyses were controlled for misreporting. A benefit of using the MDS-rec is that it allows generalisability to other populations. However, all the dietary instruments measuring past food intake are vulnerable to random and systematic measurement errors.

In conclusion, adherence to the Mediterranean diet was negatively associated with changes in abdominal adiposity measured by WC. Participants with high adherence to the Mediterranean diet were less likely to develop abdominal obesity according to R-MDS tertile distribution and MDS-rec categories. However, the association was not significant. The type of R-MDS calculation (population distribution v. dietary recommendations) did not have a strong impact on these associations. Evidence of the present study underlines the usefulness of the Mediterranean diet for the prevention of abdominal weight gain.
