(Received 27 February 2013; accepted 2 July 2013; first published online 6 September 2013)

Abstract

Let $\Omega$ be a bounded open interval, and let $p > 1$ and $q \in (0, p - 1)$. Let $m \in L^p(\Omega)$ and $0 \leq c \in L^\infty(\Omega)$. We study the existence of strictly positive solutions for elliptic problems of the form

$$
-(|u'|^{p-2}u')' + c(x)u^{p-1} = m(x)u^q \quad \text{in } \Omega,
$$

$$
u > 0 \quad \text{in } \Omega,
$$

$$
u = 0 \quad \text{on } \partial\Omega.
$$

We mention that our results are new even in the case $c \equiv 0$.

Keywords and phrases: elliptic one-dimensional problems, indefinite nonlinearities, $p$-Laplacian, strictly positive solutions.

1. Introduction

For $a < b$, let $\Omega := (a, b)$, and let $p > 1$ and $q \in (0, p - 1)$. Let $m \in L^p(\Omega)$ and $0 \leq c \in L^\infty(\Omega)$. Our aim in this paper is to study the existence of solutions for problems of the form

$$
-(|u'|^{p-2}u')' + c(x)u^{p-1} = m(x)u^q \quad \text{in } \Omega,
$$

$$
u > 0 \quad \text{in } \Omega,
$$

$$
u = 0 \quad \text{on } \partial\Omega.
$$

For applications we refer to [4] and the references therein.

When $c \equiv 0$ and $0 \neq m \geq 0$ it is known that (1.1) admits a solution. See, for example, [5, Theorem 5.1], or [2] and its references for the case $p = 2$. On the other hand, allowing $m$ to change sign and under the assumption that $m(x) \geq m_0 > 0$ in some $\overline{\Omega}' \subset \Omega$, it can be proved that the problem

$$
-(|u'|^{p-2}u')' = m(x)u^q \quad \text{in } \Omega,
$$

$$
u = 0 \quad \text{on } \partial\Omega,
$$

possesses a nontrivial nonnegative solution (see [5, Theorem 5.2], or [1, Section 5]). We note however that in general a (nontrivial) nonnegative solution of (1.2) need not
be strictly positive in $\Omega$ (in contrast to the superlinear case), and that in fact the matter of existence of strictly positive solutions for these types of problems is quite intriguing.

Recently, several noncomparable sufficient conditions for the existence of strictly positive solutions for (1.2) were exhibited in [9] under some evenness assumptions on $m$ in the case $p = 2$, and an extension of some of these results for a (linear) strongly uniformly second-order elliptic operator was given in the paper ‘Strictly positive solutions for one-dimensional nonlinear elliptic problems’, which has been submitted for publication by the current authors. We refer to it later as [KM].

Let us mention that a natural way to attack these kinds of problems is the well-known sub and supersolution method. Moreover, it is quite simple to provide arbitrarily large supersolutions (see Remark 2.1 below). To construct the strictly positive subsolutions we shall adapt and extend the approach developed in [9] and [KM]. Roughly speaking, we shall divide $\Omega$ in parts, construct ‘subsolutions’ for each of them and then find conditions on $m$, $c$, $p$ and $q$ that guarantee that they can be joined accordingly to obtain the desired subsolution. Certain conditions are presented in Theorem 3.1, and assuming that $m^{-}$ is essentially bounded, further noncomparable conditions are proved in Theorem 3.3 and Corollary 3.5.

Let us finally point out that although for the sake of simplicity we assume that $c \geq 0$, similar results can be obtained under some additional assumptions if $c$ changes sign in $\Omega$ (see Remark 3.6).

2. Preliminaries

It is well known that for $g \in L^1(\Omega)$, the problem $- (|u'|^{p-2}u')' = g$ in $\Omega$, $u = 0$ on $\partial \Omega$, admits a unique solution $u \in C^1(\overline{\Omega})$ such that $|u'|^{p-2}u'$ is absolutely continuous and that the equation holds in the pointwise sense. (See, for example, [10, 11].)

On the other side, it is also well known that if $g \in L^{p'}(\Omega)$ (where as usual $p'$ is given by $1/p + 1/p' = 1$) and $0 \leq c \in L^\infty(\Omega)$, the problem

\[
\begin{cases}
-(|v'|^{p-2}v')' + c|v|^{p-2}v = g \\
v = 0
\end{cases}
\text{ in } \Omega, \quad \text{on } \partial \Omega, \quad (2.1)
\]

has a unique weak solution $v \in W^{1,p}_0(\Omega)$, that is, satisfying

\[
\int_{\Omega} |v'|^{p-2}v' \varphi' + c|v|^{p-2}v \varphi = \int_{\Omega} g \varphi \quad \text{for all } \varphi \in W^{1,p}_0(\Omega)
\]

(see, for example, [7]). Furthermore, employing the comparison principles in, for instance, [8, Ch. 6], and recalling the above paragraph, it is easy to check the following facts: $v \in C^1(\overline{\Omega}), |v'|^{p-2}v'$ is absolutely continuous and (2.1) holds a.e. $x \in \Omega$.

We say that $0 \leq v \in W^{1,p}_0(\Omega)$ is a (weak) subsolution of (1.1) if

\[
\int_{\Omega} |v'|^{p-2}v' \varphi' + c(x)v^{p-1} \varphi \leq \int_{\Omega} m(x)u^q \varphi \quad \text{for all } 0 \leq \varphi \in W^{1,p}_0(\Omega) \quad (2.2)
\]
and \( v = 0 \) on \( \partial \Omega \); and \( 0 \leq w \in W^{1,p}_0(\Omega) \) is said to be a supersolution if (2.2) holds (with \( w \) in place of \( v \)) reversing the inequality, and \( w \geq 0 \) on \( \partial \Omega \). The well-known sub-supersolution method [5, 6] gives a solution provided there exist a subsolution \( v \) and a supersolution \( w \) satisfying \( v \leq w \).

**Remark 2.1.** Let us write as usual \( m = m^+ - m^- \) with \( m^+ = \max(m, 0) \) and \( m^- = \max(-m, 0) \). If \( m^+ \neq 0 \), one can readily verify that (1.1) admits arbitrarily large supersolutions. Indeed, let \( v \geq 0 \) be the solution of (2.1) with \( m^+ \) in place of \( g \), and let \( k \geq (\|v\|_{\infty} + 1)\gamma(p-1-q) \). Then \( k(v + 1) \) is a supersolution since \( v = k > 0 \) on \( \partial \Omega \) and

\[
-((k(v + 1))' + c(k(v + 1)))' + c(k(v + 1))^{p-1} \geq k^{p-1}m^+ \geq (k(v + 1))^{q}m \quad \text{in } \Omega.
\]

The next remark summarises some necessary facts about principal eigenvalues for problems with weight involving the \( p \)-Laplacian operator.

**Remark 2.2.** Let \( 0 \leq c \in L^{\infty}(\Omega) \) and let \( m \in L^{p'}(\Omega) \) with \( m^+ \neq 0 \). There exists a positive principal eigenvalue \( \lambda_1(m, \Omega) \) and \( \Phi \in W^{1, p}_0(\Omega) \) satisfying

\[
\begin{align*}
-(|\Phi'|^{p-2}\Phi')' + c(x)\Phi^{p-1} &= \lambda_1(m, \Omega)m(x)\Phi^{p-1} \quad \text{in } \Omega, \\
\Phi > 0 & \quad \text{in } \Omega, \\
\Phi = 0 & \quad \text{on } \partial \Omega.
\end{align*}
\]

Moreover, \( \lambda_1(m, \Omega) \) is unique and simple. (See, for example, [3] and the references therein.)

**3. Main results**

In order to avoid overloading the notation, for \( y \geq a, z \leq b \) and \( \varepsilon \geq 0 \) we set

\[
M^-_{a,\varepsilon}(y) := \int_a^y (m^-(x) + \varepsilon) \, dx, \quad M^-_{b,\varepsilon}(z) := \int_z^b (m^-(x) + \varepsilon) \, dx.
\]

If \( \varepsilon = 0 \) we simply write \( M^-_a(y) \) and \( M^-_b(z) \).

**Theorem 3.1.** Let \( m \in L^{p'}(\Omega) \) and suppose there exist \( a \leq x_0 < x_1 \leq b \) with \( 0 \neq m \geq 0 \) in \( I := (x_0, x_1) \). Let

\[
\gamma := \max\{x_1 - a, b - x_0\}
\]

and

\[
M_p := \max\left\{ M^-_a(x_1)^{2-p}\left(\int_a^{x_1} M^-_a(x) \, dx\right)^{p-1}, M^-_b(x_0)^{2-p}\left(\int_{x_0}^b M^-_b(x) \, dx\right)^{p-1}\right\}.
\]

(i) Assume \( p \geq 2 \) and \( q \in (p-2, p-1) \). If

\[
\gamma^{p-2}M_2 < \frac{p-1}{(p-1-q)^{p-1}} \frac{1}{\lambda_1(m, I)}
\]

(3.2)
and

$$\gamma^p \|c\|_{L^\infty(\Omega)} \leq \frac{(2 - p + q)(p - 1)}{(p - 1 - q)^p}$$  \hspace{1cm} (3.3)

then there exists a solution of (1.1).

(ii) Assume \( p \in (1, 2] \). If

$$M_p < \frac{(p - 1)^p}{(p - 1 - q)^{p-1}} \frac{1}{\lambda_1(m, I)}$$  \hspace{1cm} (3.4)

and

$$\gamma^p \|c\|_{L^\infty(\Omega)} \leq \left(\frac{p - 1}{p - 1 - q}\right)^p q$$  \hspace{1cm} (3.5)

then there exists a solution of (1.1).

**Proof.** Without loss of generality we assume that \( a < x_0 < x_1 < b \). (In fact, it shall be clear from the proof how to proceed if either \( x_0 = a \) or \( x_1 = b \).) Taking into account Remark 2.1 it suffices to construct a strictly positive (in \( \Omega \)) weak subsolution \( u \) for (1.1). Moreover, it is clear that it is enough to provide such subsolution for (1.1) with \( \tau m \) in place of \( m \), for some \( \tau > 0 \).

Let us prove (i). In view of (3.2) we may choose \( \varepsilon > 0 \) small enough and fix \( \tau \) such that

$$\gamma^p - 2 \frac{(p - 1 - q)^{p-1}}{p - 1} \max \left\{ \int_a^{x_1} M^-_{a,\varepsilon}(x) \, dx, \int_{x_0}^b M^-_{b,\varepsilon}(x) \, dx \right\} \leq \frac{1}{\tau} \leq \frac{1}{\lambda_1(m, I)}. \hspace{1cm} (3.6)$$

Let \( x \in [a, x_1] \) and define

$$u_1(x) := \left( \sigma \int_a^x M^-_{a,\varepsilon}(y) \, dy \right)^k,$$  \hspace{1cm} (3.7)

where

$$k := \frac{1}{p - 1 - q}, \quad \sigma := \frac{\tau \gamma^p - 2}{(p - 1)k^{p-1}}.$$  \hspace{1cm} (3.8)

We have that \( u_1(a) = 0 \) and that \( u_1 \) is strictly increasing. Also, from the first inequality in (3.6) it follows that \( \|u_1\|_\infty \leq 1 \). Let \( l := (k - 1)(p - 1) \). Since \( q > p - 2 \) it holds that \( l > 0 \). Furthermore,

$$l - 1 + p = k(p - 1), \quad l + p - 2 = kq,$$

and by (3.3) we also obtain that \( k^{p-1} l \geq \gamma^p \|c\|_\infty \). On the other hand, since \( M^-_{a,\varepsilon} \) is strictly increasing we derive that \( (x - a)M^-_{a,\varepsilon}(x) \geq \int_a^x M^-_{a,\varepsilon}(y) \, dy \) for all \( x \). Taking into account the aforementioned facts, (3.8) and that \( p \geq 2 \) and \( x_1 - a \leq \gamma \), some computations
show that
\[
-(|u'_1(x)|^{p-2}u'_1(x))' = -(k\sigma^k)^{p-1}\left(\int_a^x M_{a,\sigma}(y) \, dy\right)^{l-1} M_{a,\sigma}^-(x)^p
\]
\[
+ (p - 1)\left(\int_a^x M_{a,\sigma}(y) \, dy\right) \left|M_{a,\sigma}^-(x)\right|^{p-2}(m^-(x) + \epsilon)
\]
\[
\leq -(k\sigma^k)^{p-1}\left(\int_a^x M_{a,\sigma}(y) \, dy\right)^{k(p-1)}
\]
\[
+ \frac{(p - 1)}{\gamma p} \left(\int_a^x M_{a,\sigma}(y) \, dy\right) m^-
\]
\[
\leq -||c||_\infty \sigma^{k(p-1)}\left(\int_a^x M_{a,\sigma}(y) \, dy\right)^{k(p-1)}
\]
\[
- \tau m^- \sigma^k\left(\int_a^x M_{a,\sigma}(y) \, dy\right)^k
\]
\[
\leq -cu_1^{p-1} - \tau m^- u_1' \leq -cu_1^{p-1} + \tau mu_1^q \quad \text{in } (a, x_1).
\]

In a similar way, if for \( x \in [x_0, b] \) we set \( u_3 \) by \( u_3(x) := (\sigma^{k(b)} M_{b,\sigma}^-(y) \, dy)^k \) with \( k \) and \( \sigma \) given by (3.8), then \( u_3(b) = 0 \), \( u_3 \) is strictly decreasing, \( ||u_3||_\infty \leq 1 \) and
\[
-(|u'_3|^{p-2}u'_3) + cu_3^{p-1} \leq \tau mu_3^q \quad \text{in } (x_0, b).
\]

On the other side, let \( u_2 > 0 \) with \( ||u_2||_{L^\infty(I)} = 1 \) be the positive principal eigenfunction associated to the weight \( m \) in \( I \), that is, satisfying (2.3) with \( I \) in place of \( \Omega \). Recalling that \( m \geq 0 \) in \( I \) and that \( q < p - 1 \), from the second inequality in (3.6),
\[
-(|u'_2|^{p-2}u'_2) + cu_2^{p-1} = \lambda_1(m, I)mu_2^{p-1} \leq \tau mu_2^q \quad \text{in } I.
\]

Since
\[
u_1(a) = u_3(b) = u_2(x_0) = u_2(x_1) = 0 \quad \text{and} \quad ||u_1||_\infty, ||u_2||_\infty \leq 1 \quad \text{if } ||u_2||_\infty,
\]
arguing as in the proof of Theorem 3.1(i) in [KM] we can find \( x_0, \bar{x}_1 \in I \) with \( x_0 < \bar{x}_1 \) and such that
\[
u_1(x_0) = u_2(x_0), \quad \nu_1(\bar{x}_1) = u_3(\bar{x}_1),
\]
\[
u_1'(x_0) \leq u_2'(x_0), \quad \nu_1'(\bar{x}_1) \leq u_3'(\bar{x}_1).
\]
We now define a function \( u \) by \( u := u_1 \) in \([a, x_0] \), \( u := u_2 \) in \([x_0, \bar{x}_1] \) and \( u := u_3 \) in \([\bar{x}_1, b] \). Taking into account (3.10), a simple integration by parts yields that \( u \) is a weak subsolution for (1.1) with \( \tau m \) in place of \( m \), and, as we said at the beginning of the proof, this proves (i).

Let us prove (ii). We first pick \( \epsilon > 0 \) sufficiently small and take \( \tau \) such that
\[
\frac{(p - 1 - q)^{p-1}}{(p - 1)^p} \left(\int_a^{x_1} M_{a,\sigma}(x) \, dx\right)^{p-1} \leq \frac{1}{\tau} \leq \frac{1}{M_{a,\sigma}(x_1)^{2-p} \lambda_1(m)},
\]
\[
\frac{(p - 1 - q)^{p-1}}{(p - 1)^p} \left(\int_{x_0}^{b} M_{b,\sigma}(x) \, dx\right)^{p-1} \leq \frac{1}{\tau} \leq \frac{1}{M_{b,\sigma}(x_0)^{2-p} \lambda_1(m)}.
\]
(This is possible due to (3.4).) Let \( M_e := \max \{ M_{a,e}^{-1}(x_1), M_{b,e}(x_0) \} \). We shall build a strictly positive subsolution for (1.1) with \( \tau M_e^{p-2} m \) in place of \( m \). For \( x \in [a, x_1] \) we set \( u_1 \) as in (3.7) with
\[
 k := \frac{p-1}{p-1-q}, \quad \sigma := \frac{1}{k} \frac{\tau}{(p-1)}
\]
in place of (3.8). Again \( u_1(a) = 0, u_1 \) is strictly increasing and using the first inequality in (3.11) one can check that \( \|u_1\|_\infty \leq 1 \). Taking \( l \) as in (i) we now obtain \( l = kq \) and also as before we have \( l - 1 + p = k(p - 1) \) and \( k^{p-1}l \geq \gamma^p \|c\|_\infty \). Furthermore, recalling that \( p \leq 2 \) and arguing as in (3.9), we deduce that
\[
-(|u'(x)|^p - u_1'(x))' \leq -(k\sigma^k)^{p-1} \left( \frac{l}{\gamma^p} \left( \int_a^x M_{a,e}(y) \, dy \right)^{l-1+p} \right)
\]
\[
+ (p - 1) \left( \int_a^x M_{a,e}(y) \, dy \right)^{kq} M_e^{p-2} m^q
\]
\[
\leq -(k\sigma^k)^{p-1} \left( \frac{l}{\gamma^p} \left( \int_a^x M_{a,e}(y) \, dy \right)^{k(p-1)} \right)
\]
\[
+ (p - 1) \left( \int_a^x M_{a,e}(y) \, dy \right)^{kq} M_e^{p-2} m^q
\]
\[
\leq -\|c\|_\infty \sigma^k \left( \int_a^x M_{a,e}(y) \, dy \right)^{kq}
\]
\[
- \tau M_e^{p-2} m^q \sigma^k \left( \int_a^x M_{a,e}(y) \, dy \right)^{kq}
\]
\[
\leq -c u_1^{p-1} - \tau M_e^{p-2} m^q u_1^{q-1}
\]
\[
\leq -c u_1^{p-1} + \tau M_e^{p-2} m u_1^{q-1}
\]
in \( (a, x_1) \).

Since \( u_3 \) can be defined analogously and, taking into account the definition of \( M_e \) and the second inequality in (3.11) and (3.12), \( u_2 \) can be chosen as above (that is, as the normalised positive principal eigenfunction with respect to the weight \( m \) in \( I \)), arguing as in (i), the theorem follows.

\[\Box\]

**Remark 3.2.**

(i) Let us note that when \( m \in C(\Omega) \) the condition \( 0 \neq m \geq 0 \) in \( I \) is necessary to have a (nontrivial) nonnegative solution for (1.1).

(ii) Let us also observe that if \( p = 2 \) then (3.2) and (3.3) coincide with (3.4) and (3.5) and that the resulting conditions extend the ones in [KM] (see Theorem 3.5(ii) there).

For \( p > 1 \) and \( q \in (0, p - 1) \) we set
\[
C_{p,q} := \left( \frac{p}{p-1-q} \right)^{p-1} \frac{(p-1)(q+1)}{p-1-q}.
\]
We point out that for any $p > 1$, $\lim_{q \to p^{-1}} C_{p,q} = \infty$. We shall now assume that $m^e \in L^\infty(\Omega)$. In the following theorem we suppose that $c \neq 0$. The case $c \equiv 0$ is considered in Corollary 3.5 below.

**Theorem 3.3.** Assume $c \neq 0$. Let $m \in L^p(\Omega)$ with $m^e \in L^\infty(\Omega)$ and suppose there exist $a \leq x_0 < x_1 \leq b$ such that $0 \neq m \geq 0$ in $I := (x_0, x_1)$. Let $\gamma$ and $C_{p,q}$ be given by (3.1) and (3.13), respectively.

(i) Assume $p \geq 2$. If

$$\frac{||m^-||_{L^\infty(\Omega)}}{|c|_{L^\infty(\Omega)}} \sinh^{p}\left(\frac{||c||_{L^\infty(\Omega)}}{C_{p,q}}\right)^{1/p} \gamma \leq \frac{1}{\lambda_1(m, I)}$$

(3.14)

then there exists a solution of (1.1).

(ii) Assume $p \in (1, 2)$. If

$$\frac{||m^-||_{L^\infty(\Omega)}}{|c|_{L^\infty(\Omega)}} \left(e^{(||c||_{L^\infty(\Omega)} / C_{p,q})^{1/p} \gamma} - 1\right)^p \leq \frac{1}{\lambda_1(m, I)}$$

(3.15)

then there exists a solution of (1.1).

**Proof.** The proof follows the lines of the proof of Theorem 3.1 and hence we omit the details. We only indicate briefly how to construct $u_1$ in both (i) and (ii). Suppose first (3.14) holds. Let $\tau$ be such that

$$\frac{||m^-||_{L^\infty(\Omega)}}{|c|_{L^\infty(\Omega)}} \sinh^{p}\left(\frac{||c||_{L^\infty(\Omega)}}{C_{p,q}}\right)^{1/p} \gamma \leq \frac{1}{\tau} \leq \frac{1}{\lambda_1(m, I)}$$

(3.16)

and for $x \in [a, x_1]$ define

$$f(x) := \left(\frac{\tau||m^-||_{\infty}}{|c|_{\infty}}\right)^{1/p} \sinh\left(\frac{||c||_{\infty}}{C_{p,q}}\right)^{1/p}(x - a).$$

It is easy to check that $(C_{p,q}^{1/p} f')^2 - ((||c||_{\infty})^{1/p})^2 = (\tau||m^-||_{\infty})^{2/p}$ in $(a, x_1)$. Moreover, $f(a) = 0$, $f$ is increasing (in particular, employing (3.16) and the fact that $x_1 - a \leq \gamma$, we see that $||f||_{\infty} \leq 1$), and $f'' > 0$ in $(a, x_1)$. Let us now choose

$$k := \frac{p}{p - 1 - q}, \quad l := (k - 1)(p - 1).$$

(3.17)

Then $l - 1 = kq$, $l - 1 + p = k(p - 1)$ and $k^{p-1}l = C_{p,q}$. Define $u_1 := f^k$. Taking into account the above mentioned facts and that $p \geq 2$, we find that, in $(a, x_1)$,

$$-(|u_1'|^{p-2}u_1')' + cu^{p-1} \leq -k^{p-1}(f^{l-1}(f')^p + (p - 1)f'(f')^{p-2}f'')$$

$$+ ||c||_{\infty}f^{k(p-1)}$$

$$\leq -k^{p-1}l(f^{l-1}(f')^p + ||c||_{\infty}f^{k(p-1)})$$

$$= -f^{l-1}(C_{p,q} f')^p - ||c||_{\infty}f^p$$

$$\leq -f^{l-1}((C_{p,q} f')^2 - (||c||_{\infty})^{1/p})^{p/2}$$

(3.18)

$$= -f^{l-1} \tau \gamma ||m^-||_{\infty} \leq \tau m u_1^q.$$
Suppose now (3.15) holds. In this case we take $\tau$ and $f$ such that
\[
\|m^-\|_{L^\infty(\Omega)} (e^{\|c\|_{L^\infty(\Omega)} C_{p,q}})^{1/p} - 1)^p \leq \frac{1}{\tau} \leq \frac{1}{\lambda_1(m, I)},
\]
and
\[
f(x) := \sigma(e^{\|c\|_{L^\infty(\Omega)} / C_{p,q}} - 1),
\]
where
\[
\sigma := \left( \frac{\tau \|m^-\|_{\infty}}{\|c\|_{\infty}} \right)^{1/p}, \quad \lambda := \left( \frac{\|c\|_{\infty}}{C_{p,q}} \right)^{1/p}.
\]
Let $k$ and $l$ be given by (3.17), and let $u_1 := f^k$. Reasoning as in (3.18) yields
\[
-(|u_1'|^{p-2}u_1')' + cu^{p-1} \leq -f^{l-1}(C_{p,q}(f')^p - \|c\|_{\infty} f^p)
\]
\[
= -f^{l-1}(C_{p,q}(\sigma \lambda)^p e^{\|c\|_{\infty} \sigma (x - a)} - \|c\|_{\infty} \sigma^p (e^{\|c\|_{\infty} / C_{p,q}} - 1)^p)
\]
\[
\leq -f^{l-1}\|c\|_{\infty} \sigma^p
\]
\[
= -f^{l-1} \tau \|m^-\|_{\infty} \leq \tau mu_1^q
\]
in $(a, x_1)$.

\[\square\]

Remark 3.4. A quick look at the proof of the above theorem shows that (ii) holds for any $p > 1$. We observe however that one can verify that the inequality (3.14) is better than (3.15).

Corollary 3.5. Let $m$ be as in the above theorem and suppose $c \equiv 0$. If
\[
\frac{\|m^-\|_{L^\infty(\Omega)} \gamma^p}{C_{p,q}} \leq \frac{1}{\lambda_1(m, I)},
\]
then there exists a solution of (1.1).

Proof. It is enough to note that the left side of either (3.14) or (3.15) tends to the left side of (3.19) when $\|c\|_{\infty}$ goes to zero. Alternatively, one can also proceed as in the proof of the above theorem taking (for any $p > 1$) $f(x) := (x - a)/\gamma$.

\[\square\]

Remark 3.6. Let us suppose that $c$ changes sign in $\Omega$. An inspection of the proofs of the theorems shows that one can still argue in the same way as before, replacing $c$ by $c^+$ to construct the functions $u_1$ and $u_3$. Furthermore, if the positive principal eigenvalue $\lambda_1(m, I)$ exists (for necessary and sufficient conditions on this question, see [3, Section 2]) and if the problem (2.1) with $m^+$ in place of $g$ admits a nonnegative solution, then all the analogous results to the case $c \geq 0$ can be proved allowing $c$ to change sign in $\Omega$.
