To the Editor—Early in the coronavirus disease 2019 (COVID-19) pandemic, when testing was limited and the prevalence of severe acute respiratory coronavirus virus 2 (SARS-CoV-2) was unknown, public health recommendations restricted testing for individuals at high risk for COVID-19. Risk factors included travel history, symptoms, and close contact with someone who had a history of COVID-19. As access to testing expanded and concerns for asymptomatic transmission mounted, healthcare facilities broadened COVID-19 surveillance strategies to include testing for all asymptomatic patients requiring hospital admission or aerosol-generating procedures.

Simultaneously, national and global PPE shortages amplified concerns about high risks for to healthcare providers (HCPs). Initial studies reported infection from patients as the primary mode of transmission in up to 60% of COVID-19 infections in healthcare workers before the pandemic was recognized.1 Since that time, significant advances in testing capacity and PPE availability have been made, coupled with reassurance about the protective effects of PPE.2 Rates of COVID-19 positivity among asymptomatic patients presenting for surgery have been low throughout the pandemic: only 0.13% at an academic facility centered in one of the counties with the highest COVID-19 prevalence nationally. The total number of tests collected for asymptomatic surgical patients has exceeded 100,000 in the past 12 months.3,4 Data collected during this pandemic have demonstrated that healthcare workers are unlikely to become infected with COVID-19 when wearing appropriate PPE.2 Even in situations in which healthcare providers were performing an aerosol-generating procedure on a COVID-19–positive patient, the risk among those wearing a surgical mask and a respirator was equivalent.5 As PPE supply has increased in the United States, many healthcare institutions have begun using respirators and eye protection for all aerosol-generating procedures regardless of a patient’s SARS-CoV-2 status, further reducing the risk of unanticipated SARS-CoV-2 transmission.

Furthermore, as the incidence of a disease declines, the positive predictive value (PPV) of a test for that disease necessarily drops, even for tests with a high sensitivity and specificity. At low prevalence, the positive predictive value (PPV) of a given test is expected to be more sensitive to changes in underlying rates of disease. To illustrate this, we modeled the relationship between 7-day cumulative incidence of COVID-19 in the community (y-axis) and PPV (y-axis) for a PCR test with similar performance characteristics to those used at UCLA Health (ie, 96% sensitivity and 99% specificity),

assuming a weekly testing strategy (Fig. 1). We show that false positives exceed the number of true positives when 7-day cumulative COVID-19 incidence is below 1,030 cases per 100,000 persons. These false positives can delay care, can cause unnecessary hospital and community-setting quarantines, and can lead to repeated retesting. In addition, direct and indirect costs accrue with testing asymptomatic individuals at low risk of having COVID-19. First, COVID-19 assays require expensive machines, reagents, and technologists’ labor. According to a recent Kaiser Family Foundation survey of 93 hospitals, the median cost of a COVID-19 test was $148.6 Additional labor and supply expenses are incurred by clinics and hospitals running COVID-19 testing sites for preoperative patients. The highest 7-day average of COVID-19 cases in the United States was 533 of 100,000 in January 2020; however, rates varied substantially by locality. Currently, the 7-day average incidence is 13.65 of 100,000 in Los Angeles County and 48.95 of 100,000 nationally, with continued steady declines every day, suggesting that at this juncture in the US COVID-19 pandemic, the risk of false-positive tests and their associated consequences far outweigh the benefits of mass COVID-19 testing. The justification for maintaining such time and resource-intensive surveillance programs becomes more complex in the context of widespread use of highly effective vaccines in healthcare providers. It is time to rethink the strategy of testing asymptomatic individuals entering hospitals or receiving procedures.
