**ABSTRACT**

This article describes a protocol to be able to utilize medication-assisted treatment options for patients dependent on opioids. The first step is using a 15-day Klonopin taper for effect detox of acute opioid withdrawal. Once detoxed, the patient can start on low dose methadone or low dose Buprenorphine. Titration above 40 mg of methadone, or 8 mg of buprenorphine is not needed. Buprenorphine is utilized as the mono product, Subutex. Avoiding Suboxone eliminates the risk of reemergence of acute opioid withdrawal symptoms. A description of how to transition to Naltrexone is provided. There are some differences between Methadone and Buprenorphine in the transition to Naltrexone. Once the patient is transitioned to Naltrexone, the stage is set for the patient to be able to get off medication-assisted treatment.

**METHOD**

Two case studies; an adolescent and one adult, diagnosed with BD and the other PTSD. Both endorsed a history of symptoms indicative of TLE. Key assessment findings and screening diagnostics alerted us to the differential diagnosis of TLE. The overlap of the symptom presentation is described.

**RESULTS**

TLE and many psychiatric conditions often present with overlapping symptoms. Patients have the potential to present with absence seizures, unprovoked irritability, oppositionality, aggression, anger, paroxysmal anxiety, somatic symptoms such as headaches, nausea, burning in the abdomen, stereotyped movements or behaviors, hypergraphia bizarre or incongruous affect, symptoms of fear, disturbed sleep, tearfulness, memory problems, déjà vu, fugue states, changes in cognition, inability to concentrate, fatigue, auditory and visual hallucination and bad temper. Our differential diagnosis of TLE was confirmed with electroencephalogram (EEG). By prescribing the appropriate medications to these two individuals, they were able to experience improved moods, become more productive in society, working, attending church, family outings, etc. They were weaned off their antipsychotic medications, of which an abundance of troubling side effects is now a non-issue.

**CONCLUSIONS**

A delay in the proper diagnosis of TLE can have a significant negative impact on the adolescent and adult population. A need exists to educate mental health professionals on the overlap of symptoms of TLE and psychiatric disorders. The significant issue at hand is that they may not be receiving adequate or appropriate medications. Considering TLE in the differential diagnosis of presenting mood instability ensures our patients they are getting the basics of psychiatric care; which always emphasizes ruling out medical conditions first.
