#### Abstract

In this paper, we discuss implications of the results obtained in [5]. It was shown there that eigenvectors of the Bethe algebra of the quantum $\mathfrak{g l}_{N}$ Gaudin model are in a one-to-one correspondence with Fuchsian differential operators with polynomial kernel. Here, we interpret this fact as a separation of variables in the $\mathfrak{g l}_{N}$ Gaudin model. Having a Fuchsian differential operator with polynomial kernel, we construct the corresponding eigenvector of the Bethe algebra. It was shown in [5] that the Bethe algebra has simple spectrum if the evaluation parameters of the Gaudin model are generic. In that case, our Bethe ansatz construction produces an eigenbasis of the Bethe algebra.

2000 Mathematics Subject Classification. 81R10 (17B10 81R12 34M35)

1. Introduction. Generally speaking, separation of variables in a quantum integrable model is a reduction of a multi-dimensional spectral problem to a suitable one-dimensional problem. For example, the famous Sklyanin's separation of variables for the $\mathfrak{g l}_{2}$ Gaudin model [10] is a reduction of the diagonalization problem of the Gaudin Hamiltonians, acting on a tensor product of $\mathfrak{g l}_{2}$-modules, to the problem of finding a second-order Fuchsian differential operator with polynomial kernel and prescribed singularities. Having such a differential operator, Sklyanin constructs an eigenvector of the Hamiltonians.

It has been proved recently in [5] that the eigenvectors of the Bethe algebra of the $\mathfrak{g l}_{N}$ Gaudin model are in a bijective correspondence with $N$ th-order Fuchsian differential operators with polynomial kernel and prescribed singularities. This reduces the multi-dimensional problem of the diagonalization of the Bethe algebra to the onedimensional problem of finding the corresponding Fuchsian differential operators. In that respect, 'the variables are separated'.

Having an eigenvector of the Bethe algebra, one has an effective way to construct the corresponding Fuchsian operator (see [2,5] and Theorem 2.1). In the opposite
direction, the assignment of an eigenvector to a Fuchsian operator is not explicit in [5]. In this paper, having a Fuchsian differential operator with polynomial kernel, we construct the corresponding eigenvector of the Bethe algebra. Our construction of an eigenvector from a differential operator can be viewed as a (generalized) Bethe ansatz construction (cf. [1, 6-8]).

It has been proved in [5] that the action of the Bethe algebra on a tensor product of irreducible finite-dimensional evaluation $\mathfrak{g l}_{N}[t]$-modules has simple spectrum provided the evaluation points are generic. In that case, our construction of eigenvectors of the Bethe algebra produces an eigenbasis of the Bethe algebra, thus showing the completeness of the Bethe ansatz.

## 2. Eigenvectors of Bethe algebra.

2.1. Lie algebra $\mathfrak{g l}_{N}$. Let $e_{i j}, i, j=1, \ldots, N$, be the standard generators of the Lie algebra $\mathfrak{g l}_{N}$, satisfying the relations $\left[e_{i j}, e_{s k}\right]=\delta_{j s} e_{i k}-\delta_{i k} e_{s j}$.

Let $M$ be a $\mathfrak{g l}_{N}$-module. A vector $v \in M$ has weight $\lambda=\left(\lambda_{1}, \ldots, \lambda_{N}\right) \in \mathbb{C}^{N}$ if $e_{i i} v=\lambda_{i} v$ for $i=1, \ldots, N$. A vector $v$ is called singular if $e_{i j} v=0$ for $1 \leqslant i<j \leqslant N$.

We denote by $(M)_{\lambda}$ the subspace of $M$ of weight $\lambda$, by $(M)^{\text {sing }}$ the subspace of $M$ of all singular vectors and by $(M)_{\lambda}^{\text {sing }}$ the subspace of $M$ of all singular vectors of weight $\lambda$.

Denote by $L_{\lambda}$ the irreducible finite-dimensional $\mathfrak{g l}_{N}$-module with highest weight $\lambda$. Any finite-dimensional $\mathfrak{g l}_{N}$ weight module $M$ is isomorphic to the direct sum $\bigoplus_{\lambda} L_{\lambda} \otimes$ $(M)_{\lambda}^{\text {sing }}$, where the spaces $(M)_{\lambda}^{\text {sing }}$ are considered as trivial $\mathfrak{g l}_{N}$-modules.

The $\mathfrak{g l}_{N}$-module $L_{(1,0, \ldots, 0)}$ is the standard $N$-dimensional vector representation of $\mathfrak{g l}_{N}$, which we denote by $V$. We choose a highest weight vector in $V$ and denote it by $v_{+}$.

A $\mathfrak{g l}_{N}$-module $M$ is called polynomial if it is isomorphic to a sub-module of $V^{\otimes n}$ for some $n$.

A sequence of integers $\lambda=\left(\lambda_{1}, \ldots, \lambda_{N}\right)$ such that $\lambda_{1} \geqslant \lambda_{2} \geqslant \ldots \geqslant \lambda_{N} \geqslant 0$ is called a partition with at most $N$ parts. Set $|\lambda|=\sum_{i=1}^{N} \lambda_{i}$. Then it is said that $\lambda$ is a partition of $|\lambda|$.

The $\mathfrak{g l}_{N}$-module $V^{\otimes n}$ contains the module $L_{\lambda}$ if and only if $\lambda$ is a partition of $n$ with at most $N$ parts.
2.2. Current algebra $\mathfrak{g l}_{N}[t]$. Let $\mathfrak{g l}_{N}[t]=\mathfrak{g l}_{N} \otimes \mathbb{C}[t]$ be the Lie algebra of $\mathfrak{g l}_{N^{-}}$ valued polynomials with the pointwise commutator. We call it the current algebra. We identify the Lie algebra $\mathfrak{g l}_{N}$ with the sub-algebra $\mathfrak{g l}_{N} \otimes 1$ of constant polynomials in $\mathfrak{g l} l_{N}[t]$. Hence, any $\mathfrak{g l}_{N}[t]$-module has the canonical structure of a $\mathfrak{g l}_{N}$-module.

It is convenient to collect elements of $\mathfrak{g l}_{N}[t]$ in generating series of a formal variable $u$. For $g \in \mathfrak{g l}_{N}$, set

$$
g(u)=\sum_{s=0}^{\infty}\left(g \otimes t^{s}\right) u^{-s-1}
$$

For each $a \in \mathbb{C}$, there exists an automorphism $\rho_{a}$ of $\mathfrak{g l}_{N}[t], \rho_{a}: g(u) \mapsto g(u-$ $a)$. Given a $\mathfrak{g l}_{N}[t]$-module $M$, we denote by $M(a)$ the pull-back of $M$ through the automorphism $\rho_{a}$. As $\mathfrak{g l}_{N}$-modules, $M$ and $M(a)$ are isomorphic by the identity map.

We have the evaluation homomorphism, ev : $\mathfrak{g l}_{N}[t] \rightarrow \mathfrak{g l}_{N}$, ev : $g(u) \mapsto g u^{-1}$. Its restriction to the sub-algebra $\mathfrak{g l}_{N} \subset \mathfrak{g l}_{N}[t]$ is the identity map. For any $\mathfrak{g l}_{N}$-module $M$, we denote by the same letter the $\mathfrak{g l}_{N}[t]$-module, obtained by pulling $M$ back through the evaluation homomorphism. For each $a \in \mathbb{C}$, the $\mathfrak{g l}_{N}[t]$-module $M(a)$ is called an evaluation module.
2.3. Bethe algebra. Given an $N \times N$ matrix $A$ with possibly non-commuting entries $a_{i j}$, we define its row determinant to be

$$
\operatorname{rdet} A=\sum_{\sigma \in S_{N}}(-1)^{\sigma} a_{1 \sigma(1)} a_{2 \sigma(2)} \ldots a_{N \sigma(N)}
$$

Let $\partial$ be the operator of differentiation in variable $u$. Define the universal differential operator $\mathcal{D}^{\mathcal{B}}$ by

$$
\mathcal{D}^{\mathcal{B}}=\operatorname{rdet}\left(\begin{array}{cccc}
\partial-e_{11}(u) & -e_{21}(u) & \ldots & -e_{N 1}(u) \\
-e_{12}(u) & \partial-e_{22}(u) & \ldots & -e_{N 2}(u) \\
\ldots & \ldots & \ldots & \ldots \\
-e_{1 N}(u) & -e_{2 N}(u) & \ldots & \partial-e_{N N}(u)
\end{array}\right) .
$$

It is a differential operator in variable $u$, whose coefficients are formal power series in $u^{-1}$ with coefficients in $U\left(\mathfrak{g l}_{N}[t]\right)$,

$$
\mathcal{D}^{\mathcal{B}}=\partial^{N}+\sum_{i=1}^{N} B_{i}(u) \partial^{N-i},
$$

where

$$
B_{i}(u)=\sum_{j=i}^{\infty} B_{i j} u^{-j}
$$

and $B_{i j} \in U\left(\mathfrak{g l}_{N}[t]\right), \quad i=1, \ldots, N, j \in \mathbb{Z}_{\geqslant i}$. We call the unital sub-algebra of $U\left(\mathfrak{g l}_{N}[t]\right)$ generated by $B_{i j}, i=1, \ldots, N, j \in \mathbb{Z}_{\geqslant i}$ the Bethe algebra and denote it by $\mathcal{B}$.

By $[1,11]$, the algebra $\mathcal{B}$ is commutative and commutes with the sub-algebra $U\left(\mathfrak{g l}_{N}\right) \subset U\left(\mathfrak{g l}_{N}[t]\right)$.

As a sub-algebra of $U\left(\mathfrak{g l}_{N}[t]\right)$, the algebra $\mathcal{B}$ acts on any $\mathfrak{g l}_{N}[t]$-module $M$. Since $\mathcal{B}$ commutes with $U\left(\mathfrak{g l}_{N}\right)$, it preserves the subspace of singular vectors ( $\left.M\right)^{\text {sing }}$ as well as weight subspaces of $M$. Therefore, the subspace $(M)_{\lambda}^{\text {sing }}$ is $\mathcal{B}$-invariant for any weight $\lambda$.

Let $\lambda^{(1)}, \ldots, \lambda^{(k)}, \lambda$ be partitions with at most $N$ parts and $b_{1}, \ldots, b_{k}$ distinct complex numbers. We are interested in the action of the Bethe algebra $\mathcal{B}$ on the tensor product of evaluation modules $\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)$ and more precisely, on the subspace $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$.

Note that the subspace $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ is zero-dimensional unless $|\lambda|=$ $\sum_{s=1}^{k}\left|\lambda^{(s)}\right|$.
2.4. Fuchsian differential operators and eigenvectors of Bethe algebra. Denote $\boldsymbol{\Lambda}=\left(\lambda^{(1)}, \ldots, \lambda^{(k)}\right)$ and $\boldsymbol{b}=\left(b_{1}, \ldots, b_{k}\right)$. Let $\Delta_{\boldsymbol{\Lambda}, \lambda, \boldsymbol{b}}$ be the set of all monic Fuchsian
differential operators of order $N$,

$$
\mathcal{D}=\partial^{N}+\sum_{i=1}^{N} h_{i}^{\mathcal{D}}(u) \partial^{N-i},
$$

with the following properties:
(a) The singular points of $\mathcal{D}$ are at $b_{1}, \ldots, b_{k}$ and $\infty$ only.
(b) The exponents of $\mathcal{D}$ at $b_{s}, s=1, \ldots, k$, are equal to $\lambda_{N}^{(s)}, \lambda_{N-1}^{(s)}+1, \ldots, \lambda_{1}^{(s)}+$ $N-1$.
(c) The exponents of $\mathcal{D}$ at $\infty$ are equal to $1-N-\lambda_{1}, 2-N-\lambda_{2}, \ldots,-\lambda_{N}$.
(d) The kernel of the operator $\mathcal{D}$ consists of polynomials only.

Note that the set $\Delta_{\Lambda, \lambda, \boldsymbol{b}}$ is empty unless $|\lambda|=\sum_{s=1}^{k}\left|\lambda^{(s)}\right|$.
Let $M$ be a $\mathfrak{g l}_{N}[t]-$ module and $v$ an eigenvector of the Bethe algebra $\mathcal{B} \subset U\left(\mathfrak{g l}_{N}[t]\right)$ acting on $M$. Then for any coefficient $B_{i}(u)$ of the universal differential operator $\mathcal{D}^{\mathcal{B}}$ we have $B_{i}(u) v=h_{i}(u) v$, where $h_{i}(u)$ is a scalar series. We call the scalar differential operator

$$
\mathcal{D}_{v}^{\mathcal{B}}=\partial^{N}+\sum_{i=1}^{N} h_{i}(u) \partial^{N-i}
$$

the differential operator associated with the eigenvector $v$.
THEOREM 2.1. Let $v \in\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ be an eigenvector of the Bethe algebra; then $\mathcal{D}_{v}^{\mathcal{B}} \in \Delta_{\Lambda, \lambda, b}$. Moreover, the assignment $v \mapsto \mathcal{D}_{v}^{\mathcal{B}}$ is a bijective correspondence between the set of eigenvectors of the action of the Bethe algebra on $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ (considered up to multiplication by non-zero numbers) and the set $\Delta_{\boldsymbol{\Lambda}, \lambda, \boldsymbol{b}}$.

The first statement is Theorem 4.1 in [2] (cf. [4]). The second statement is Theorem 7.1 in [5].

The goal of this paper is to construct the inverse bijection.

## 3. Schubert cell and universal weight function.

3.1. The cell $\Omega_{\lambda}$. Let $N, d \in \mathbb{Z}_{>0}, N \leqslant d$. Let $\mathbb{C}_{d}[u]$ be the space of polynomials in $u$ of degree less than $d$. We have $\operatorname{dim} \mathbb{C}_{d}[u]=d$. Let $\operatorname{Gr}(N, d)$ be the Grassmannian of all $N$-dimensional subspaces in $\mathbb{C}_{d}[u]$.

Given a partition $\lambda=\left(\lambda_{1}, \ldots, \lambda_{N}\right)$ such that $\lambda_{1} \leqslant d-N$, introduce a sequence

$$
P=\left\{d_{1}>d_{2}>\cdots>d_{N}\right\}, \quad d_{i}=\lambda_{i}+N-i
$$

and denote by $\Omega_{\lambda}$ the subset of $\operatorname{Gr}(N, d)$ consisting of all $N$-dimensional subspaces $X \subset \mathbb{C}_{d}[u]$ such that for every $i=1, \ldots, N$, the subspace $X$ contains a polynomial of degree $d_{i}$.

In other words, $\Omega_{\lambda}$ consists of subspaces $X \subset \mathbb{C}_{d}[u]$ with a basis $\left\{f_{1}(u), \ldots, f_{N}(u)\right\}$ of the form

$$
f_{i}(u)=u^{d_{i}}+\sum_{j=1, d_{i}-j \notin P}^{d_{i}} f_{i j} u^{d_{i}-j} .
$$

For a given $X \in \Omega_{\lambda}$, such a basis is unique. The basis $\left\{f_{1}(u), \ldots, f_{N}(u)\right\}$ will be called the flag basis of the subspace $X$.

The set $\Omega_{\lambda}$ is a (Schubert) cell isomorphic to an affine space of dimension $|\lambda|$ with coordinate functions $f_{i j}$.

For $X \in \Omega_{\lambda}$, we denote by $\mathcal{D}_{X}$ the monic scalar differential operator of order $N$ with kernel $X$. We call $\mathcal{D}_{X}$ the differential operator associated with $X$.
3.2. Generic points of $\Omega_{\lambda}$. For $g_{1}, \ldots, g_{l} \in \mathbb{C}[u]$, introduce the Wronskian by the formula

$$
\operatorname{Wr}\left(g_{1}(u), \ldots, g_{l}(u)\right)=\operatorname{det}\left(\begin{array}{cccc}
g_{1}(u) & g_{1}^{\prime}(u) & \ldots & g_{1}^{(l-1)}(u) \\
g_{2}(u) & g_{2}^{\prime}(u) & \ldots & g_{2}^{(l-1)}(u) \\
\ldots & \ldots & \ldots & \ldots \\
g_{l}(u) & g_{l}^{\prime}(u) & \ldots & g_{l}^{(l-1)}(u)
\end{array}\right)
$$

For $X \in \Omega_{\lambda}$, let $\left\{f_{1}(u), \ldots, f_{N}(u)\right\}$ be the flag basis of $X$. Introduce the polynomials $\left\{y_{0}(u), y_{1}(u), \ldots, y_{N-1}(u)\right\}$, by the formula

$$
y_{a}(u) \prod_{a<i<j \leqslant N}\left(\lambda_{i}-\lambda_{j}\right)=\operatorname{Wr}\left(f_{a+1}(u), \ldots, f_{N}(u)\right), \quad a=0, \ldots, N .
$$

Set

$$
\begin{equation*}
l_{a}=\sum_{b=a+1}^{N} \lambda_{b}, \quad a=0, \ldots, N \tag{1}
\end{equation*}
$$

Clearly, $l_{0}=|\lambda|$ and $l_{N}=0$.
For each $a=0, \ldots, N-1$, the polynomial $y_{a}(u)$ is a monic polynomial of degree $l_{a}$. Denote $t_{1}^{(a)}, \ldots, t_{l_{a}}^{(a)}$ the roots of the polynomial $y_{a}(u)$ and

$$
\begin{equation*}
\boldsymbol{t}_{X}=\left(t_{1}^{(0)}, \ldots, t_{l_{0}}^{(0)}, \ldots, t_{1}^{(N-1)}, \ldots, t_{l_{N-1}}^{(N-1)}\right) \tag{2}
\end{equation*}
$$

We say that $\boldsymbol{t}_{X}$ are the root coordinates of $X$.
We say that $X \in \Omega_{\lambda}$ is generic if all roots of the polynomials $y_{0}(u)$, $y_{1}(u), \ldots, y_{N-1}(u)$ are simple, and for each $a=1, \ldots, N-1$, the polynomials $y_{a-1}(u)$ and $y_{a}(u)$ do not have common roots.

If $X$ is generic, then the root coordinates $\boldsymbol{t}_{X}$ satisfy the Bethe ansatz equations [7]:

$$
\sum_{j^{\prime}=1}^{l_{a-1}} \frac{1}{t_{j}^{(a)}-t_{j^{\prime}}^{(a-1)}}-\sum_{\substack{j^{\prime}=1 \\ j^{\prime} \neq j}}^{l_{a}} \frac{2}{t_{j}^{(a)}-t_{j^{\prime}}^{(a)}}+\sum_{j^{\prime}=1}^{l_{a+1}} \frac{1}{t_{j}^{(a)}-t_{j^{\prime}}^{(a+1)}}=0
$$

Here the equations are labelled by $a=1, \ldots, N-1, j=1, \ldots, l_{a}$.
Conversely, if $\boldsymbol{t}=\left(t_{1}^{(0)}, \ldots, t_{l_{0}}^{(0)}, \ldots, t_{1}^{(N-1)}, \ldots, t_{l_{N-1}}^{(N-1)}\right)$ satisfy the Bethe ansatz equations, then there exists a unique $X \in \Omega_{\lambda}$ such that $X$ is generic and $t$ are its root coordinates (see (2)). This $X$ is determined by the following construction (see [7]). Set

$$
\chi^{a}(u, \boldsymbol{t})=\sum_{j=1}^{l_{a-1}} \frac{1}{u-t_{j}^{(a-1)}}-\sum_{i=1}^{l_{a}} \frac{1}{u-t_{j}^{(a)}}, \quad a=1, \ldots, N .
$$

Then

$$
\mathcal{D}_{X}=\left(\partial-\chi^{1}(u, \boldsymbol{t})\right) \ldots\left(\partial-\chi^{N}(u, \boldsymbol{t})\right) .
$$

Lemma 3.1. Generic points form a Zariski open subset of $\Omega_{\lambda}$.
The lemma follows, for example, from part (i) of Theorem 6.1 in [6].
3.3. Universal weight function. Let $\lambda$ be a partition with at most $N$ parts. Let $l_{0}, \ldots, l_{N}$ be the numbers defined in (1). Denote $n=l_{0}, l=l_{1}+\cdots+l_{N-1}$ and $\boldsymbol{l}=$ $\left(l_{1}, \ldots, l_{N-1}\right)$.

Consider the weight subspace $\left(V^{\otimes n}\right)_{\lambda}$ of the $n$th tensor power of the vector representation of $\mathfrak{g l}_{N}$ and the space $\mathbb{C}^{l+n}$ with coordinates $\boldsymbol{t}=\left(t_{1}^{(0)}, \ldots\right.$, $\left.t_{l_{0}}^{(0)}, \ldots, t_{1}^{(N-1)}, \ldots, t_{l_{N-1}}^{(N-1)}\right)$.

In this section we remind the construction of a rational map $\omega: \mathbb{C}^{l+n} \rightarrow\left(V^{\otimes n}\right)_{\lambda}$, called the universal weight function (see [9]).

A basis of $V^{\otimes n}$ is formed by the vectors

$$
e_{J} v=e_{j_{1}, 1} v_{+} \otimes \cdots \otimes e_{j_{n}, 1} v_{+},
$$

where $J=\left(j_{1}, \ldots, j_{n}\right)$ and $1 \leqslant j_{s} \leqslant N$ for $s=1, \ldots, N$. A basis of $\left(V^{\otimes n}\right)_{\lambda}$ is formed by the vectors $e_{J} v$ such that $\#\left\{s \mid j_{s}>i\right\}=l_{i}$ for every $i=1, \ldots, N-1$. Such a $J$ will be called $\boldsymbol{l}$-admissible.

The universal weight function has the form

$$
\omega(\boldsymbol{t})=\sum_{J} \omega_{J}(\boldsymbol{t}) e_{J} v
$$

where the sum is over the set of all $\boldsymbol{l}$-admissible $J$, and the function $\omega_{J}(\boldsymbol{t})$ is defined below.

For an admissible $J$, define $S(J)=\left\{s \mid j_{s}>1\right\}$, and for $i=1, \ldots, N-1$, define

$$
S_{i}(J)=\left\{s \mid 1 \leqslant s \leqslant n, \quad 1 \leqslant i<j_{s}\right\} .
$$

Then $\left|S_{i}(J)\right|=l_{i}$.
Let $B(J)$ be the set of sequences $\boldsymbol{\beta}=\left(\beta_{1}, \ldots, \beta_{N-1}\right)$ of bijections $\beta_{i}: S_{i}(J) \rightarrow$ $\left\{1, \ldots, l_{i}\right\}, i=1, \ldots, N-1$. Then $|B(J)|=\prod_{a=1}^{N-1} l_{a}!$.

For $s \in S(J)$ and $\beta \in B(J)$, introduce the rational function

$$
\omega_{s, \beta}(t)=\frac{1}{t_{\beta_{1}(s)}^{(1)}-t_{s}^{(0)}} \prod_{i=2}^{j_{1}-1} \frac{1}{t_{\beta_{i}(s)}^{(i)}-t_{\beta_{i-1}(s)}^{(i-1)}}
$$

and define

$$
\omega_{J}(\boldsymbol{t})=\sum_{\beta \in B(J)} \prod_{s \in S(J)} \omega_{s, \beta} .
$$

Example 1. Let $n=2$ and $\boldsymbol{l}=(1,1,0, \ldots, 0)$. Then

$$
\omega(\boldsymbol{t})=\frac{1}{\left(t_{1}^{(2)}-t_{1}^{(1)}\right)\left(t_{1}^{(1)}-t_{1}^{(0)}\right)} e_{3,1} v_{+} \otimes v_{+}+\frac{1}{\left(t_{1}^{(2)}-t_{1}^{(1)}\right)\left(t_{1}^{(1)}-t_{2}^{(0)}\right)} v_{+} \otimes e_{3,1} v_{+} .
$$

Theorem 3.2. Let $X \in \Omega_{\lambda}$ be a generic point with root coordinates $\boldsymbol{t}_{X}$. Consider the value $\omega\left(\boldsymbol{t}_{X}\right)$ of the universal weight function $\omega: \mathbb{C}^{l+n} \rightarrow\left(V^{\otimes n}\right)_{\lambda}$ at $\boldsymbol{t}_{X}$. Consider $V^{\otimes n}$ as the $\mathfrak{g l}_{N}[t]$-module $\otimes_{s=1}^{n} V\left(t_{s}^{(0)}\right)$. Then
(i) the vector $\omega\left(\boldsymbol{t}_{X}\right)$ belongs to $\left(V^{\otimes n}\right)_{\lambda}^{\text {sing }}$;
(ii) the vector $\omega\left(\boldsymbol{t}_{X}\right)$ is an eigenvector of the Bethe algebra $\mathcal{B}$, acting on $\otimes_{s=1}^{n} V\left(t_{s}^{(0)}\right)$. Moreover, $\mathcal{D}_{\omega\left(\boldsymbol{t}_{X}\right)}^{\mathcal{B}}=\mathcal{D}_{X}$, where $\mathcal{D}_{\omega\left(\boldsymbol{t}_{X}\right)}^{\mathcal{B}}$ and $\mathcal{D}_{X}$ are the differential operators associated with the eigenvector $\omega\left(\boldsymbol{t}_{X}\right)$ and the point $X \in \Omega_{\lambda}$, respectively.

Part (i) is proved in [1] and [8]. Part (i) also follows directly from Theorem 6.16.2 in [9]. Part (ii) is proved in [3].

Remark. For a generic point $X \in \Omega_{\lambda}$ the differential operator $\mathcal{D}_{X}$ has the following properties (continued from Section 2.4):
(e) The singular points of $\mathcal{D}_{X}$ are at $t_{1}^{(0)}, \ldots, t_{n}^{(0)}$ and $\infty$ only.
(f) The exponents of $\mathcal{D}_{X}$ at $t_{s}^{(0)}, s=1, \ldots, n$, are equal to $0,1, \ldots, N-2, N$.
(g) The exponents of $\mathcal{D}_{X}$ at $\infty$ are equal to $1-N-\lambda_{1}, 2-N-\lambda_{2}, \ldots,-\lambda_{N}$.
(h) The kernel of the operator $\mathcal{D}_{X}$ consists of polynomials only.

On the other hand, Theorem 2.1, applied to the $\mathfrak{g l}_{N}[t]$-module $\otimes_{s=1}^{n} V\left(t_{s}^{(0)}\right)$, yields that for any eigenvector $v$ of the Bethe algebra $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{n} V\left(t_{s}^{(0)}\right)\right)_{\lambda}^{\text {sing }}$, the differential operator $\mathcal{D}_{v}^{\mathcal{B}}$ has properties (e)-(h).

Therefore, the universal weight function and the assignment $\mathcal{D}_{X} \mapsto X \mapsto \omega\left(\boldsymbol{t}_{X}\right)$ allows us to reverse the correspondence $v \mapsto \mathcal{D}_{v}^{\mathcal{B}}$ of Theorem 2.1 for the case of the $\mathfrak{g l}_{N}[t]$-module $\otimes_{s=1}^{n} V\left(t_{s}^{(0)}\right)$ under the condition that $X \in \Omega_{\lambda}$ is generic. Our goal is to generalize this construction to the case of a $\mathfrak{g l}_{N}[t]$-module $\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)$ and an arbitrary differential operator $\mathcal{D} \in \Delta_{\boldsymbol{\Lambda}, \lambda, \boldsymbol{b}}$.

## 4. Construction of an eigenvector from a differential operator.

4.1. Epimorphism $F_{\lambda}$. Let $\lambda^{(1)}, \ldots, \lambda^{(k)}, \lambda$ be partitions with at most $N$ parts such that $|\lambda|=\sum_{s=1}^{k}\left|\lambda^{(s)}\right|$ and $b_{1}, \ldots, b_{k}$ distinct complex numbers. Denote $n=|\lambda|$ and $n_{s}=\left|\lambda^{(s)}\right|, s=1, \ldots, k$.

For $s=1, \ldots, k$, let $F_{s}: V^{\otimes n_{s}} \rightarrow L_{\lambda^{(s)}}$ be an epimorphism of $\mathfrak{g l}_{N}$-modules. Then

$$
\begin{equation*}
F_{1} \otimes \cdots \otimes F_{k}: \otimes_{s=1}^{k} V\left(b_{s}\right)^{\otimes n_{s}} \rightarrow \otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right) \tag{1}
\end{equation*}
$$

is an epimorphism of $\mathfrak{g l}_{N}[t]$-module, which induces an epimorphism of $\mathcal{B}$-modules

$$
F:\left(\otimes_{s=1}^{k} V\left(b_{s}\right)^{\otimes n_{s}}\right)_{\lambda}^{\text {sing }} \rightarrow\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}
$$

4.2. Main result. Let $\mathcal{D}^{0}$ be an element of $\Delta_{\boldsymbol{\Lambda}, \lambda, \boldsymbol{b}}$. Let $X^{0}$ be the kernel of $\mathcal{D}^{0}$. Then $X^{0}$ is a point of the cell $\Omega_{\lambda}$. Choose a germ of an algebraic curve $X(\epsilon)$ in $\Omega_{\lambda}$ such that $X(0)=X^{0}$ and $X(\epsilon)$ are generic points of $\Omega_{\lambda}$ for all non-zero $\epsilon$. Let $t(\epsilon)$ be the root coordinates of $X(\epsilon)$. The algebraic functions $t_{1}^{(0)}(\epsilon), \ldots, t_{n}^{(0)}(\epsilon)$ are determined up to permutation. Order them in such a way that the first $n_{1}$ of them tend to $b_{1}$ as $\epsilon \rightarrow 0$; the next $n_{2}$ coordinates tend to $b_{2}$; and so on until the last $n_{k}$ coordinates tend to $b_{k}$.

For every non-zero $\epsilon$, the vector $v(\epsilon)=\omega(\boldsymbol{t}(\epsilon))$ belongs to $\left(V^{\otimes n}\right)_{\lambda}^{\text {sing }}$. This vector is an eigenvector of the Bethe algebra $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{n} V\left(t_{s}^{(0)}(\epsilon)\right)\right)_{\lambda}^{\text {sing }}$, and we have $\mathcal{D}_{v(\epsilon)}^{\mathcal{B}}=\mathcal{D}_{X(\epsilon)}$ (see Theorem 3.2).

The vector $v(\epsilon)$ depends on $\epsilon$ algebraically. Let $v(\epsilon)=v_{0} \epsilon^{a_{0}}+v_{1} \epsilon^{a_{1}}+\cdots$ be its Puiseux expansion, where $v_{0}$ is the leading non-zero coefficient.

Theorem 4.1. For a generic choice of the maps $F_{1}, \ldots, F_{k}$, the vector $F\left(v_{0}\right)$ is non-zero. Moreover, $F\left(v_{0}\right)$ is an eigenvector of the Bethe algebra $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$, and $\mathcal{D}_{F\left(v_{0}\right)}^{\mathcal{B}}=\mathcal{D}^{0}$.

Proof. For any element $B \in \mathcal{B}$, the action of $B$ on the $U\left(\mathfrak{g l}_{N}[t]\right)$-module $\otimes_{s=1}^{n} V\left(z_{s}\right)$ determines an element of $\operatorname{End}\left(V^{\otimes n}\right)$, polynomially depending on $z_{1}, \ldots, z_{n}$. Since for every non-zero $\epsilon$, the vector $v(\epsilon)$ is an eigenvector of $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{n} V\left(t_{s}^{(0)}(\epsilon)\right)\right)_{\lambda}^{\text {sing }}$, and since $\mathcal{D}_{v(\epsilon)}^{\mathcal{B}}=\mathcal{D}_{X(\epsilon)}$, we conclude that the vector $v_{0}$ is an eigenvector of $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{k} V\left(b_{s}\right)^{\otimes n_{s}}\right)_{\lambda}^{\text {sing }}$, and $\mathcal{D}_{v_{0}}^{\mathcal{B}}=\mathcal{D}^{0}$.

The $\mathfrak{g l}_{N}[t]$-module $\otimes_{s=1}^{k} V\left(b_{s}\right)^{\otimes n_{s}}$ is a direct sum of irreducible $\mathfrak{g l}_{N}[t]$-modules of the form $\otimes_{s=1}^{k} L_{\boldsymbol{\mu}^{(s)}}\left(b_{s}\right)$, where $\left|\boldsymbol{\mu}^{(s)}\right|=n_{s}, s=1, \ldots, k$. Since $\mathcal{D}^{0} \in \Delta_{\boldsymbol{\Lambda}, \lambda, \boldsymbol{b}}$, the vector $v_{0}$ belongs to the component of the type $\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)$. Therefore, for generic choice of the maps $F_{1}, \ldots, F_{k}$, the vector $F\left(v_{0}\right)$ is non-zero.

Since the map $F_{1} \otimes \cdots \otimes F_{k}$ (see (1)) is a homomorphism of $\mathfrak{g l}_{N}[t]$-modules, the vector $F\left(v_{0}\right)$ is an eigenvector of the Bethe algebra $\mathcal{B}$, acting on $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$, and $\mathcal{D}_{F\left(v_{0}\right)}^{\mathcal{B}}=\mathcal{D}^{0}$.

Remark. The direction of the vector $v_{0}$ can depend on the choice of the algebraic curve $X(\epsilon)$ in $\Omega_{\lambda}$. However, Theorem 2.1 yields that the direction of the vector $F\left(v_{0}\right)$ does not depend on either the choice of the curve $X(\epsilon)$ or the choice of the maps $F_{1}, \ldots, F_{k}$.

Given $\mathcal{D} \in \Delta_{\Lambda, \lambda, \boldsymbol{b}}$, denote by $w(\mathcal{D})$ the vector $F\left(v_{0}\right) \in\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ constructed from $\mathcal{D}$ in this section. The vector $w(\mathcal{D})$ is defined up to multiplication by a non-zero number. The assignment $\mathcal{D} \mapsto w(\mathcal{D})$ gives the correspondence, which is inverse to the correspondence $v \mapsto \mathcal{D}_{v}^{\mathcal{B}}$ in Theorem 2.1.
4.3. Completeness of Bethe ansatz for $\mathfrak{g l}_{N}$ Gaudin model. The construction of the vector $w(\mathcal{D}) \in\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ from a differential operator $\mathcal{D} \in \Delta_{\Lambda, \lambda, b}$ can be viewed as a (generalized) Bethe ansatz construction for the $\mathfrak{g l}_{N}$ Gaudin model (cf. the Bethe ansatz constructions in $[\mathbf{1 , 6 - 8 ]}$ ).

The following statement is contained in Theorem 6.1, Corollary 6.2 and Corollary 6.3 of [5].

Theorem 4.2. If $b_{1}, \ldots, b_{k}$ are distinct real numbers, then the action of the Bethe algebra on $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$ is diagonalizable and has simple spectrum.

Hence, for generic complex numbers $b_{1}, \ldots, b_{k}$, there exists an eigenbasis of the action of the Bethe algebra on $\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }}$. This eigenbasis is unique up to permutation of vectors and multiplication of vectors by non-zero numbers.

Corollary 4.3. If $b_{1}, \ldots, b_{k}$ are distinct real numbers or $b_{1}, \ldots, b_{k}$ are generic complex numbers, then the collection of vectors

$$
\left\{w(\mathcal{D}) \in\left(\otimes_{s=1}^{k} L_{\lambda^{(s)}}\left(b_{s}\right)\right)_{\lambda}^{\text {sing }} \mid \mathcal{D} \in \Delta_{\Lambda, \lambda, b}\right\}
$$

is an eigenbasis of the action of the Bethe algebra.
