# GENERALISED VARIATIONAL-LIKE INEQUALITIES AND A GAP FUNCTION 

Q.H. Ansari and J.C. Yao

In this paper, we study the existence of solutions of generalised variational-like inequality problems by using a generalised form of the Fan-KKM-Theorem. We also introduce a gap function for generalised variational-like inequalities.

## 1. Introduction and preliminaries

Let $E$ be a topological vector space with dual $E^{*}$ and let $\left\langle E^{*}, E\right\rangle$ be the dual system of $E^{*}$ and $E$. We denote by $2^{X}$ the family of all nonempty subsets of a set $X$ and by $\mathcal{F}(X)$ the family of all nonempty finite subsets of $X$. If $X$ is a subset of a topological vector space $E$, we shall denote by $\bar{X}$ the closure of $X$ in $E$, and by $\operatorname{co}(\mathrm{X})$ the convex hull of $X$. Let $C$ and $K$ be nonempty subsets of $E$ and $E^{*}$, respectively. Given two maps $\theta: C \times K \rightarrow E^{*}$ and $\eta: C \times C \rightarrow E$, and a multifunction $T: C \rightarrow 2^{K}$, then we consider the following generalised variational-like inequality problems:

Problem 1. Find $\bar{x} \in C$ and $\bar{s} \in T(\bar{x})$ such that

$$
\begin{equation*}
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad y \in C \tag{1}
\end{equation*}
$$

The vector $\bar{x}$ is called a strong solution of Problem 1. We denote by $S(P 1)$ the set of all such vectors $\bar{x}$.

Problem 2. Find $\bar{x} \in C$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\begin{equation*}
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0 \tag{2}
\end{equation*}
$$

The solution $\bar{x}$ of this problem is called a weak solution of Problem 1. We denote by $S(P 2)$ the set of all solutions of this problem.

[^0]Problem 3. Find $\bar{x} \in C$ such that

$$
\begin{equation*}
\langle\theta(y, t),(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad y \in C \text { and } t \in T(y) \tag{3}
\end{equation*}
$$

We denote by $S(P 3)$ the set of all its solutions.
Inequalities (1), (2) and (3) are known as generalised variational-like inequalities (in short, GVLI). Problem 1 was introduced by Parida and Sen [13] in finite dimensional spaces. They also showed its relation with convex mathematical programming. It was further studied by Yao $[19,20]$ with applications in complementarity problems.

When $\theta(x, s)=s$, for any $x \in C$, Problem 1 was considered by Boss [1], Ding [6] and Siddiqi et al [17].

When $\theta(x, s)=s$ and $\eta(x, y)=x-y$, for any $x, y \in C$ and $s \in T(x)$, the above three problems were studied by Crouzeix [5] in the setting of finite dimensional spaces. In this case, Problem 1 was studied for example by Browder [2], Chowdhury and Tan [3, 4], Ding and Tarafdar [7], Fang and Peterson [9], Saigal [14], Shih and Tan [15], Siddiqi and Ansari [16], Tan [18], Yao [21], and Yen [22].

In Section 2, we first prove that $S(P 1)=S(P 2)=S(P 3)$ under certain conditions. Then we define a gap function [10], which provides an optimisation problem formulation, for the generalised variational-like inequality (GVLI)(3). In Section 3, we consider a more general problem which includes Problem 2 as a special case.

Let $C$ and $K$ be nonempty subsets of $E$ and $E^{*}$, respectively. Let $\varphi: K \times C \times C \rightarrow$ $\mathbb{R}$ be a function and $T: C \rightarrow 2^{K}$ be a multifunction. Then we consider the following problem known as a generalised implicit variational problem:
(GIVP) Find $\bar{x} \in C$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\begin{equation*}
\varphi(\bar{s}, \bar{x}, y) \leqslant 0 \tag{4}
\end{equation*}
$$

We prove the existence of its solution by using a result of Chowdhury and Tan [3] which is a generalised form of the Fan-KKM Theorem [8]. As an application, we use our results to prove the existence of solutions of (GVLI).

Let $X, Y$ be subsets of a vector space $E$ such that $\operatorname{co}(\mathrm{X}) \subset Y$. Then the multifunction $F: X \rightarrow 2^{Y}$ is called a KKM-map if for each $A \in \mathcal{F}(X), \operatorname{co}(\mathrm{A}) \subset \bigcup_{x \in A} F(x)$.

The graph of $F$, denoted by $\mathcal{G}(F)$, is

$$
\mathcal{G}(F)=\{(x, y) \in X \times Y: x \in X, y \in F(x)\}
$$

We shall use the following result of Chowdhury and Tan [3] in proving our main results in Section 3.

Theorem A. Let $C$ be a nonempty convex set in a topological vector space $E$. Let $G: C \rightarrow 2^{C}$ be a KKM-map such that
(i) $\overline{G\left(y_{0}\right)}$ is compact for some $y_{0} \in C$,
(ii) for each $A \in \mathcal{F}(C)$ with $y_{0} \in A$ and each $y \in \operatorname{co}(\mathrm{~A}), G(y) \cap \operatorname{co}(\mathrm{A})$ is closed in $\operatorname{co}(\mathrm{A})$, and
(iii) for each $A \in \mathcal{F}(C)$ with $y_{0} \in A$,

$$
\overline{\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right)} \cap \operatorname{co}(\mathrm{A})=\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right) \cap \operatorname{co}(\mathrm{A})
$$

Then $\bigcap_{y \in C} G(y) \neq \emptyset$.
The following Kneser minimax theorem [12] will be used in Section 2.
Theorem B. Let $X$ be a nonempty convex subset of a vector space, and let $Y$ be a nonempty compact convex subset of a Hausdorff topological vector space. Suppose that the functional $f: X \times Y \rightarrow \mathbb{R}$ is such that, for each fixed $x \in X, f(x, \cdot)$ is lower semicontinuous and convex, and for each fixed $y \in Y, f(\cdot, y)$ is concave. Then

$$
\min _{y \in Y} \sup _{x \in X} f(x, y)=\sup _{x \in X} \min _{y \in Y} f(x, y)
$$

## 2. A GAP FUNCTION FOR (GVLI)

Throughout in this paper, unless specified otherwise, $E$ is a topological vector space with dual $E^{*}$.

Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty subset of $E^{*}$. Given two functions $\theta: C \times K \rightarrow E^{*}$ and $\eta: C \times C \rightarrow E$, the multifunction $T: C \rightarrow 2^{K}$ is called:
(i) $\eta$-pseudomonotone with respect to $\theta$ if for every pair of points $x \in K$, $y \in K$ and for all $s \in T(x), t \in T(y)$, we have

$$
\langle\theta(x, s), \eta(x, y)\rangle \leqslant 0 \text { implies }\langle\theta(y, t), \eta(x, y)\rangle \leqslant 0
$$

(ii) $V$-hemicontinuous with respect to $\theta$ and $\eta$ if for all $x, y \in K$, $0<\lambda<1$ and $s_{\lambda} \in T(\lambda y+(1-\lambda) x)$, there exists $s \in T(x)$ such that $\left\langle\theta\left(x, s_{\lambda}\right), \eta(x, y)\right\rangle$ converges to $\langle\theta(x, s), \eta(x, y)\rangle$ as $\lambda$ tends to $0^{+}$.
It is clear that $S(P 1) \subseteq S(P 2)$. By using Theorem B, we prove $S(P 2) \subseteq S(P 1)$.
Proposition 1. Let $E$ be a Hausdorff topological vector space with dual $E^{*}$ and let $C$ and $K$ be nonempty convex subsets of $E$ and $E^{*}$, respectively. Let $T: C \rightarrow$ $2^{K}$ be a compact convex valued multifunction. Assume that
(a) for each $x, y \in C, s \mapsto\langle\theta(x, s), \eta(x, y)\rangle$ is lower semicontinuous and convex;
(b) for each $x \in K$ and $s \in T(x), y \mapsto\langle\theta(x, s), \eta(x, y)\rangle$ is concave.

Then $S(P 2) \subseteq S(P 1)$.
Proof: Let $\bar{x} \in C$ be a solution of Problem 2. Then for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0
$$

Define a functional $f: C \times T(\bar{x}) \rightarrow \mathbb{R}$ by

$$
f(y, s)=\langle\theta(\bar{x}, s), \eta(\bar{x}, y)\rangle
$$

By assumption (a), for each $y \in C$, the functional $s \mapsto f(y, s)$ is lower semicontinuous and convex, and by assumption (b), for each $s \in T(\bar{x})$, the functional $y \mapsto f(y, s)$ is concave. Then by Theorem B, we have

$$
\begin{aligned}
\min _{s \in T(\bar{x})} \sup _{y \in C}\langle\theta(\bar{x}, s), \eta(\bar{x}, y)\rangle & =\sup _{y \in C} \min _{s \in T(\bar{x})}\langle\theta(\bar{x}, s), \eta(\bar{x}, y)\rangle \\
& =\sup _{y \in C}\left[\inf _{s \in T(\bar{x})}\langle\theta(\bar{x}, s), \eta(\bar{x}, y)\rangle\right] \\
& \leqslant 0
\end{aligned}
$$

Since $T(\bar{x})$ is compact, there exists a point $\bar{s} \in T(\bar{x})$ such that

$$
\sup _{y \in C}[\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle] \leqslant 0
$$

and hence

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad y \in C
$$

that is, $\bar{x} \in S(P 1)$.
Proposition 2. Let $C$ and $K$ be nonempty subsets of $E$ and $E^{*}$, respectively. If $T: C \rightarrow 2^{K}$ is $\eta$-pseudomonotone with respect to $\theta$, then $S(P 1) \subseteq S(P 3)$.

Proposition 3. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty subset of $E^{*}$. Let $\theta(\cdot, \cdot)$ and $\eta(\cdot, \cdot)$ be concave in their first and second arguments, respectively, such that $\eta(x, x)=0$ for all $x \in C$. If $T: C \rightarrow 2^{K}$ is $V$-hemicontinuous with respect to $\theta$ and $\eta$, then $S(P 3) \subseteq S(P 2)$.

Proof: Let $\bar{x} \in S(P 3)$. Then

$$
\langle\theta(y, t), \eta(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad y \in C \quad \text { and } \quad t \in T(y)
$$

By the convexity of $C$, for any $\lambda \in(0,1)$, we have

$$
\left\langle\theta\left(\lambda y+(1-\lambda) \bar{x}, s_{\lambda}\right), \eta(\bar{x}, \lambda y+(1-\lambda) \bar{x})\right\rangle \leqslant 0, \quad \text { for all } \quad s_{\lambda} \in T(\lambda y+(1-\lambda) \bar{x})
$$

Since $\theta(\cdot, \cdot)$ and $\eta(\cdot, \cdot)$ are concave in their first and second arguments, respectively, and $\eta(x, x)=0$ for all $x \in C$, we have

$$
\begin{aligned}
0 & \geqslant\left\langle\theta\left(\lambda y+(1-\lambda) \bar{x}, s_{\lambda}\right), \eta(\bar{x}, \lambda y+(1-\lambda) \bar{x})\right\rangle \\
& \geqslant \lambda^{2}\left\langle\theta\left(y, s_{\lambda}\right), \eta(\bar{x}, y)\right\rangle+(1-\lambda) \lambda\left\langle\theta\left(\bar{x}, s_{\lambda}\right), \eta(\bar{x}, y)\right\rangle
\end{aligned}
$$

Dividing by $\lambda>0$, we get

$$
0 \geqslant \lambda\left\langle\theta\left(y, s_{\lambda}\right), \eta(\bar{x}, y)\right\rangle+(1-\lambda)\left\langle\theta\left(\bar{x}, s_{\lambda}\right), \eta(\bar{x}, y)\right\rangle
$$

Taking $\lambda \rightarrow 0^{+}$and by $V$-hemicontinuity with respect to $\theta$ and $\eta$ of $T$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0
$$

and hence $\bar{x} \in S(P 2)$.
By combining Propositions 1-3, we have the following result.
Theorem 1. Let $E$ be a Hausdorff topological vector space with dual $E^{*}$ and let $C$ and $K$ be nonempty convex subsets of $E$ and $E^{*}$, respectively. Let $T: C \rightarrow 2^{K}$ be compact convex valued, $\eta$-pseudomonotone with respect to $\theta$ and $V$-hemicontinuous with respect to $\theta$ and $\eta$. Let $\theta(\cdot, \cdot)$ and $\eta(\cdot, \cdot)$ be concave in their first and second arguments, respectively, such that $\eta(x, x)=0$ for all $x \in C$. Let $s \mapsto\langle\theta(x, s), \eta(x, y)\rangle$, for all $x, y \in C$, be lower semicontinuous and convex. Then $S(P 1)=S(P 2)=S(P 3)$.

Let $C$ be a nonempty subset of $E$. Then a functional $f: C \rightarrow \mathbb{R} \cup\{-\infty,+\infty\}$ is called a gap function for (GVLI) if
(i) $f(x) \geqslant 0$, for all $x \in C$,
(ii) $f(x)=0$ if and only if $x$ is a solution of (GVLI).

Now, we define a functional $g: C \rightarrow \mathbb{R} \cup\{-\infty,+\infty\}$ as follows:

$$
\begin{equation*}
g(x)=\sup [\langle\theta(y, t), \eta(x, y)\rangle: y \in C \quad \text { and } \quad t \in T(y)] . \tag{5}
\end{equation*}
$$

We also set

$$
m=\inf _{x \in C} g(x) \quad \text { and } \quad M=\{x \in C: g(x)=m\}
$$

Theorem 2. Let $C$ be a nonempty subset of $E$ and let $\eta(x, x)=0$ for all $x \in C$. Then $g$ as defined by (5) is a gap function for (GVLI)(3).

Proof: (i) Since $\langle\theta(x, s), \eta(x, x)\rangle=0$ for all $x \in C$ and $s \in T(x)$, we have

$$
\begin{equation*}
g(x) \geqslant 0, \quad \text { for all } \quad x \in C \tag{6}
\end{equation*}
$$

(ii) Suppose that $\bar{x} \in C$ is a solution of (GVLI)(3), then

$$
\langle\theta(y, t), \eta(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad t \in T(y)
$$

and hence

$$
\begin{equation*}
\sup [\langle\theta(y, t), \eta(\bar{x}, y)\rangle: y \in C \quad \text { and } \quad t \in T(y)] \leqslant 0 \tag{7}
\end{equation*}
$$

This implies that $g(\bar{x}) \leqslant 0$. Combining (6) and (7) we get

$$
\begin{equation*}
g(\bar{x})=0 \tag{8}
\end{equation*}
$$

Conversely, let $g(\bar{x})=0$. From (5), we have

$$
g(\bar{x}) \geqslant\langle\theta(y, t), \eta(\bar{x}, y)\rangle, \quad \text { for all } \quad y \in C \quad \text { and } \quad t \in T(y)
$$

and hence

$$
\langle\theta(y, t), \eta(\bar{x}, y)\rangle \leqslant 0, \quad \text { for all } \quad y \in C \quad \text { and } \quad t \in T(y)
$$

Therefore, $\bar{x} \in C$ is a solution of (GVLI)(3).
Theorem 3. Let $C$ be nonempty subset of $E$ and let $\eta(x, x)=0$, for all $x \in C$. If $S(P 3) \neq \emptyset$, then $m=0$ and $M=S(P 3)$.

Proof: Let $S(P 3) \neq \emptyset$. Then from (8), $m=0$.
Let $\bar{x} \in C$ be a solution of (GVLI)(3). Then $g(\bar{x})=0$. But from (6), we have $g(x) \geqslant 0$ for all $x \in C$, and hence $g(\bar{x}) \leqslant g(x)$ for all $x \in C$. Therefore, $\bar{x} \in M$.

Conversely, assume that $\bar{x} \in M$. Then $g(\bar{x})=0$ and thus $\bar{x} \in S(P 3)$. Hence $M=S(P 3)$.

Combining Theorems 1-3, we have the following result.
Theorem 4. Assume that all the hypotheses of Theorem 1 are satisfied and if $m=0$ and $M \neq \emptyset$, then $M=S(P 1)=S(P 2)=S(P 3)$.

## 3. Existence results

We first prove the existence of solution of (GIVP) by using Theorem A.
Theorem 5. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty subset of $E^{*}$. Let $\varphi: K \times C \times C \rightarrow \mathbb{R}$ be a function and $T: C \rightarrow 2^{K}$ be a multifunction. Assume that
$1^{0}$ for each $A \in \mathcal{F}(C)$ and each $x \in \operatorname{co}(\mathrm{~A}), \min _{y \in A} \varphi(s, x, y) \leqslant 0$ for all $s \in$ $T(x) ;$
$2^{0}$ for each $A \in \mathcal{F}(C)$ and each $y \in \operatorname{co}(\mathrm{~A})$,
$G(y) \cap \operatorname{co}(\mathrm{A})=\{x \in \operatorname{co}(\mathrm{~A}):$ there exists $s \in T(x)$ such that $\varphi(s, x, y) \leqslant 0\}$ is closed in $\operatorname{co}(\mathrm{A})$;
$3^{0}$ for each $A \in \mathcal{F}(C)$ and each $x^{*}, y \in \operatorname{co}(\mathrm{~A})$ and for every net $\left\{x_{\alpha}\right\}_{\alpha \in \Gamma}$ in $C$ converging to $x^{*}$, if there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for all $\alpha \in \Gamma$, for which

$$
\varphi\left(s_{\alpha}, x_{\alpha}, y\right) \leqslant 0, \quad \text { for all } \quad \alpha \in \Gamma
$$

then there exists $s^{*} \in T\left(x^{*}\right)$ such that $\varphi\left(s^{*}, x^{*}, y\right) \leqslant 0$;
$4^{0}$ there exists a nonempty closed and compact subset $D$ of $C$ and $z \in D$ such that

$$
\varphi\left(s^{\prime}, x^{\prime}, z\right)>0, \quad \text { for all } \quad x^{\prime} \in C \backslash D \text { and } s^{\prime} \in T\left(x^{\prime}\right)
$$

Then there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that $\varphi(\bar{s}, \bar{x}, y) \leqslant 0$.

Proof: We define the multifunction $G: C \rightarrow 2^{C}$ by $G(y)=\{x \in C:$ there exists $s \in T(x)$ such that $\varphi(s, x, y) \leqslant 0\}$, for each $y \in C$. We show first that $G$ is a KKM-map.

Suppose that $G$ is not a KKM-map. Then for some finite subset $\left\{y_{1}, \ldots, y_{n}\right\}$ of $C$ and $\lambda_{i} \geqslant 0$ for all $i=1, \ldots, n$ with $\sum_{i=1}^{n} \lambda_{i}=1$, we have $x_{0}=\sum_{i=1}^{n} \lambda_{i} y_{i} \notin \bigcup_{i=1}^{n} G\left(y_{i}\right)$. Then, for all $s_{0} \in T\left(x_{0}\right)$,

$$
\varphi\left(s_{0}, x_{0}, y_{i}\right)>0, \quad \text { for all } \quad i=1, \ldots, n
$$

and so

$$
\min _{1 \leqslant i \leqslant n} \varphi\left(s_{0}, x_{0}, y_{i}\right)>0
$$

which contradicts the assumption $1^{0}$. Hence $G$ is a KKM-map. Moreover, we have,
(i) $G(z) \subset D$ by assumption $4^{0}$, so that $\overline{G(z)} \subset \bar{D}=D$ and hence $\overline{G(z)}$ is compact in $C$;
(ii) for each $A \in \mathcal{F}(C)$ with $z \in A$ and each $y \in \operatorname{co}(\mathrm{~A})$,
$G(y) \cap \operatorname{co}(\mathrm{A})=\{x \in \operatorname{co}(\mathrm{~A}):$ there exists $s \in T(x)$ such that $\varphi(s, x, y) \leqslant 0\}$ is closed in $\operatorname{co}(\mathrm{A})$ by assumption $2^{0}$.
(iii) for each $A \in \mathcal{F}(C)$ with $z \in A$, if $x^{*} \in \overline{\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right)} \cap \operatorname{co}(\mathrm{A})$ then $x^{*} \in$ $\overline{\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right)}$ and $x^{*} \in \operatorname{co}(\mathrm{~A})$, and there is a net $\left\{x_{\alpha}\right\}$ in $\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)$ such that $x_{\alpha}$ converges to $x^{*}$. For each $y \in \operatorname{co}(\mathrm{~A})$, there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for which

$$
\varphi\left(s_{\alpha}, x_{\alpha}, y\right) \leqslant 0, \text { for all } \alpha \in \Gamma
$$

From assumption $3^{0}$, there exists $s^{*} \in T\left(x^{*}\right)$ such that $\varphi\left(s^{*}, x^{*}, y\right) \leqslant 0$. It follows that $x^{*} \in\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right) \cap \operatorname{co}(\mathrm{A})$ and hence

$$
\overline{\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right)} \cap \operatorname{co}(\mathrm{A})=\left(\bigcap_{y \in \operatorname{co}(\mathrm{~A})} G(y)\right) \cap \operatorname{co}(\mathrm{A})
$$

By Theorem A, we have $\bigcap_{y \in C} G(y) \neq \emptyset$. Therefore, noting that $\bigcap_{y \in C} G(y) \subseteq G(z) \subseteq$ $D$, there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that $\varphi(\bar{s}, \bar{x}, y) \leqslant 0$.

THEOREM 6. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty compact subset of $E^{*}$. Let $\varphi: K \times C \times C \rightarrow \mathbb{R}$ be a function and $T: C \rightarrow 2^{K}$ be a multifunction such that its graph is closed. Assume that
$1^{0}$ for each $A \in \mathcal{F}(C)$ and each $x \in \operatorname{co}(\mathrm{~A}), \min _{y \in A} \varphi(s, x, y) \leqslant 0$ for all $s \in$ $T(x)$;
$2^{0} \quad$ for each $A \in \mathcal{F}(C)$ and each $y \in \operatorname{co}(\mathrm{~A}), \varphi(\cdot, \cdot, y)$ is lower semicontinuous on $K \times \operatorname{co}(\mathrm{A})$;
$3^{0}$ for each $A \in \mathcal{F}(C)$ and each $x^{*}, y \in \operatorname{co}(\mathrm{~A})$ and for every net $\left\{x_{\alpha}\right\}_{\alpha \in \Gamma}$ in $C$ converging to $x^{*}$, if there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for all $\alpha \in \Gamma$, for which

$$
\varphi\left(s_{\alpha}, x_{\alpha}, y\right) \leqslant 0 \text { for all } \alpha \in \Gamma
$$

then there exists $x^{*} \in T\left(x^{*}\right)$ such that $\varphi\left(s^{*}, x^{*}, y\right) \leqslant 0$;
$4^{0}$ there exists a nonempty closed and compact subset $D$ of $C$ and $z \in D$ such that

$$
\varphi\left(s^{\prime}, x^{\prime}, z\right)>0, \quad \text { for all } y \in C \backslash D \text { and } s^{\prime} \in T\left(x^{\prime}\right)
$$

Then there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that $\varphi(\bar{s}, \bar{x}, y) \leqslant 0$.

Proof: If we prove that for each $A \in \mathcal{F}(C)$ with $z \in A$ and each $y \in \operatorname{co}(\mathrm{~A})$,

$$
G(y) \cap \operatorname{co}(\mathrm{A})=\{x \in \operatorname{co}(\mathrm{~A}): \text { there exists } s \in T(x) \text { such that } \varphi(s, x, y) \leqslant 0\}
$$

is closed in $\operatorname{co}(\mathrm{A})$ then from Theorem 5, we get the result.
Indeed, let $\left\{x_{\beta}\right\}_{\beta \in \Lambda}$ be a net in $G(y) \cap \operatorname{co}(\mathrm{A})$ such that $x_{\beta}$ converges to $x$. Then $x \in \operatorname{co}(\mathrm{~A})$, because $\operatorname{co}(\mathrm{A})$ is compact (see [3, p.922]). Since $x_{\beta} \in G(y) \cap \operatorname{co}(\mathrm{A})$, there exist $s_{\beta} \in T\left(x_{\beta}\right)$ such that $\varphi\left(s_{\beta}, x_{\beta}, y\right) \leqslant 0$. Since $T(C)$ is contained in a compact set
$K$, we may assume that $s_{\beta}$ converges to some $s \in K$. Then from the closed graph of $T$. we have $s \in T(x)$. Since $\varphi(\cdot, \cdot, y)$, for each $y \in \operatorname{co}(\mathrm{~A})$, is lower semicontinuous, we get

$$
0 \geqslant \liminf _{\beta} \varphi\left(s_{\beta}, x_{\beta}, y\right) \geqslant \varphi(s, x, y)
$$

and hence $x \in G(y) \cap \operatorname{co}(\mathrm{A})$, as desired.
As applications of Theorem 5 and Theorem 6 , we have the following results:
Corollary 1. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty subset of $E^{*}$. Let $\theta: C \times K \rightarrow E^{*}$ and $\eta: C \times C \rightarrow E$ be functions and $T: C \rightarrow 2^{K}$ be a multifunction. Assume that
$1^{0}$ for each $A \in \mathcal{F}(C)$ and each $x \in \operatorname{co}(\mathrm{~A}), \min _{y \in A}\langle\theta(x, s), \eta(x, y)\rangle \leqslant 0$ for all $s \in T(x) ;$
$2^{0}$ for each $A \in \mathcal{F}(C)$ and each $y \in \operatorname{co}(\mathrm{~A})$, the set

$$
\{x \in \operatorname{co}(\mathrm{~A}): \text { there exists } s \in T(x) \text { such that }\langle\theta(x, s), \eta(x, y)\rangle \leqslant 0\}
$$

is closed in $\operatorname{co}(\mathrm{A})$;
$3^{0}$ for each $A \in \mathcal{F}(C)$ and each $x^{*}, y \in \operatorname{co}(A)$ and for every net $\left\{x_{\alpha}\right\}_{\alpha \in \Gamma}$ in $C$ converging to $x^{*}$, if there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for all $\alpha \in \Gamma$, for which

$$
\left\langle\theta\left(x_{\alpha}, s_{\alpha}\right), \eta\left(x_{\alpha}, y\right)\right\rangle \leqslant 0, \quad \text { for all } \quad \alpha \in \Gamma
$$

then there exists $s^{*} \in T\left(x^{*}\right)$ such that $\left\langle\theta\left(x^{*}, s^{*}\right), \eta\left(x^{*}, y\right)\right\rangle \leqslant 0$;
$4^{0}$ there exists a nonempty closed and compact subset $D$ of $C$ and $z \in D$ such that

$$
\left\langle\theta\left(x^{\prime}, s^{\prime}\right), \eta\left(x^{\prime}, z\right)\right\rangle>0, \quad \text { for all } y \in C \backslash D \text { and } s^{\prime} \in T\left(x^{\prime}\right)
$$

Then there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0
$$

Proof: By taking $\varphi(s, x, y)=\langle\theta(x, s), \eta(x, y)\rangle$ in Theorem 5, we get the result.

Corollary 2. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty compact subset of $E^{*}$. Let $\theta: C \times K \rightarrow E^{*}$ and $\eta: C \times C \rightarrow E$ be functions and $T: C \rightarrow 2^{K}$ be a multifunction such that its graph is closed. Assume that
$1^{0}$ for each $A \in \mathcal{F}(C)$ and each $x \in \operatorname{co}(\mathrm{~A}), \min _{y \in A}\langle\theta(x, s), \eta(x, y)\rangle \leqslant 0$ for all $s \in T(x) ;$
$2^{0}$
for each $A \in \mathcal{F}(C)$ and each $y \in \operatorname{co}(\mathrm{~A}),\langle\theta(x, s), \eta(x, y)\rangle$ is lower semicontinuous in $(s, x) \in K \times \operatorname{co}(\mathrm{A})$;
$3^{0}$ for each $A \in \mathcal{F}(C)$ and each $x^{*}, y \in \operatorname{co}(\mathrm{~A})$ and for every net $\left\{x_{\alpha}\right\}_{\alpha \in \Gamma}$ in $C$ converging to $x^{*}$, if there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for all $\alpha \in \Gamma$, for which

$$
\left\langle\theta\left(x_{\alpha}, s_{\alpha}\right), \eta\left(x_{\alpha}, y\right)\right\rangle \leqslant 0, \quad \text { for all } \quad \alpha \in \Gamma
$$

then there exists $s^{*} \in T\left(x^{*}\right)$ such that $\left\langle\theta\left(x^{*}, s^{*}\right), \eta\left(x^{*}, y\right)\right\rangle \leqslant 0$;
$4^{0}$ there exists a nonempty closed and compact subset $D$ of $C$ and $z \in D$ such that

$$
\left\langle\theta\left(x^{\prime}, s^{\prime}\right), \eta\left(x^{\prime}, z\right)\right\rangle>0, \quad \text { for all } y \in C \backslash D \text { and } s^{\prime} \in T\left(x^{\prime}\right)
$$

Then there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0
$$

Proof: By taking $\varphi(s, x, y)=\langle\theta(x, s), \eta(x, y)\rangle$ in Theorem 6, we get the result.

Corollary 3. Let $C$ be a nonempty convex subset of $E$ and $K$ be a nonempty compact subset of $E^{*}$. Let $\theta: C \times K \rightarrow E^{*}$ and $\eta: C \times C \rightarrow E$ be functions and $T: C \rightarrow 2^{K}$ be a multifunction such that its graph is closed. Assume that
$1^{0} \quad\langle\theta(x, s), \eta(x, x)\rangle=0$ for all $x \in C$ and $s \in T(x) ;$
$2^{0} \quad y \mapsto\langle\theta(x, s), \eta(x, y)\rangle$ is quasiconcave for each fixed $x \in C$ and $s \in T(x)$;
$3^{0}$ for each $A \in \mathcal{F}(C)$ and each $y \in \operatorname{co}(\mathrm{~A}),\langle\theta(x, s), \eta(x, y)\rangle$ is lower semicontinuous in $(s, x) \in K \times \operatorname{co}(\mathrm{A})$;
$4^{0}$ for each $A \in \mathcal{F}(C)$ and each $x^{*}, y \in \operatorname{co}(\mathrm{~A})$ and for every net $\left\{x_{\alpha}\right\}_{\alpha \in \Gamma}$ in $C$ converging to $x^{*}$, if there exists a net $\left\{s_{\alpha}\right\}$ in $K$ with $s_{\alpha} \in T\left(x_{\alpha}\right)$ for all $\alpha \in \Gamma$, for which

$$
\left\langle\theta\left(x_{\alpha}, s_{\alpha}\right), \eta\left(x_{\alpha}, y\right)\right\rangle \leqslant 0, \quad \text { for all } \quad \alpha \in \Gamma,
$$

then there exists $s^{*} \in T\left(x^{*}\right)$ such that $\left\langle\theta\left(x^{*}, s^{*}\right), \eta\left(x^{*}, y\right)\right\rangle \leqslant 0$;
$5^{0}$ there exists a nonempty closed and compact subset $D$ of $C$ and $z \in D$ such that

$$
\left\langle\theta\left(x^{\prime}, s^{\prime}\right), \eta\left(x^{\prime}, z\right)\right\rangle>0, \quad \text { for all } \quad y \in C \backslash D \text { and } s^{\prime} \in T\left(x^{\prime}\right)
$$

Then there exists $\bar{x} \in D$ such that for each $y \in C$, there exists $\bar{s} \in T(\bar{x})$ such that

$$
\langle\theta(\bar{x}, \bar{s}), \eta(\bar{x}, y)\rangle \leqslant 0
$$

Proof: In view of assumptions $1^{0}$ and $2^{0}$, it is easy to prove that the multifunction $G$ in the proof of Theorem 5 is a KKM-map. By taking $\theta(s, x, y)=$ $\langle\theta(x, s), \eta(x, y)\rangle$ in Corollary 2, we get the result.
