Abstract

To investigate whether the effect of maternal dietary protein on offspring lipid metabolism is mediated by microRNA (miRNA), fourteen Meishan sows were fed either low-protein (LP, half of standard protein (SP) level, n 7) or SP (n 7) diets throughout gestation and lactation periods. PPAR-γ and C/EBP/ enhancer-binding protein-β (C/EBP-β) protein expression was evaluated. The expression of miRNA predicted to directly target PPAR-γ and C/EBP-β in the subcutaneous fat of offspring at weaning age was determined, and the functions of these potential miRNA were verified. The results showed that piglet body weight and back fat thickness were significantly decreased in the LP group compared with the SP group (P<0.05). The protein level of PPAR-γ was significantly decreased and C/EBP-β protein expression was also decreased, though not significantly (P=0.056), in the subcutaneous fat of the LP group. Furthermore, miRNA expression analysis showed that miR-130b, targeting the PPAR-γ 3'-untranslated region (UTR), and miR-374b, targeting the C/EBP-β 3'-UTR, were significantly increased in the LP group compared with the SP group; other candidate regulatory miRNA were expressed similarly in both groups. Dual luciferase activity assay results indicated that miR-130b directly recognised and bound to the 3'-UTR of PPAR-γ and thereby suppressed PPAR-γ gene expression. Similar results were found for miR-374b and the 3'-UTR of C/EBP-β. The present study showed that miR-130b and miR-374b are involved in the effect of maternal dietary protein on offspring lipid metabolism in pigs. These results shed new light on our understanding of the maternal effect on offspring lipid deposition.

Key words: Meishan pigs: MicroRNA: Maternal dietary protein: PPAR-γ: CCAAT/enhancer-binding protein-β

During the past two decades, lipid metabolism has received a great deal of attention due to the marked increase in the global prevalence of adult and childhood obesity. In this context, it is of particular interest that a range of epidemiological, clinical and animal studies have shown that maternal nutrition has a long-term influence on offspring lipid metabolism state(1–3). It has been demonstrated that dietary protein intake during gestation and lactation is associated with offspring obesity(4–6). Although the evidence supporting a link between the fetal environment and propensity towards later lipid metabolism disorders is growing, the molecular mechanisms underlying this phenomenon are still largely unclear.

MicroRNAs (miRNA) are a class of small, endogenous, single-stranded non-coding RNA molecules that act as post-transcriptional modulators of gene expression in eukaryotes(7). Recent studies have revealed that miRNA are crucial regulators of adipogenesis(8–10). To date, several individual miRNA have been described to regulate lipid metabolism. For example, miR-335 was reported to be closely correlated with the levels of adipocyte differentiation markers, such as PPAR-γ, adipocyte lipid-binding protein and fatty acid synthesis in 3T3-L1 adipocytes(11). The overexpression of miR-27 specifically inhibits adipocyte formation without affecting myogenic differentiation(12), and both miR-27a and miR-27b are negative regulators of adipogenesis(12,13). Knock-down of miR-378 and/or miR-378* decreases TAG accumulation(14). Though progress has been achieved in understanding the physiological roles of miRNA in adipocytes, the roles of miRNA in mediating the effects of maternal nutrition on offspring lipid metabolism remains poorly understood. Furthermore, over 228 miRNA have been identified in pigs to date (http://www.miRbase.org), but very few of the predicted targets have been experimentally validated.

CCAAT/enhancer-binding protein-β (C/EBP-β) and PPAR-γ are well-established transcription factors involved in lipid metabolism during adipogenesis(15–18). The PPAR-γ is the master regulator of adipocyte differentiation and insulin sensitivity(19). C/EBP-β is also known to directly influence adipocyte development(20). One previous study has suggested that the adipogenic differentiation of 3T3-L1 cells can be blocked via the inhibition of C/EBP-β and PPAR-γ-dependent pathways(21). In the present study, we employed the Meishan sow as a

Abbreviations: C/EBP-β, CCAAT/enhancer-binding protein-β, LP, low protein; miRNA, microRNA, SP, standard protein; UTR, untranslated region.

model. This indigenous Chinese pig breed is famed for its high reproduction, good meat quality, resistance to roughage, high body fat deposition and slow growth. The low protein (LP) group was fed a LP diet containing 6% protein during pregnancy followed by 7% protein during lactation, whereas the standard protein (SP) group received 12 and 14% protein during pregnancy and lactation, respectively. PPAR-γ and C/EBP-β were chosen as the primary genes analysed to investigate their role in regulating offspring lipid deposition. The expression levels of miRNA predicted to target these two genes were evaluated, and the functions of these candidate miRNA were verified. These results provide further evidence for a thorough understanding of the maternal effect on offspring lipid metabolism and are of clinical relevance in light of the on-going worldwide obesity epidemic.

Materials and methods

Animals and subcutaneous fat sampling

The animal experiments were carried out in the National Meishan Pig Preservation and Breeding Farm at the Jiangsu Polytechnic College of Agriculture and Forestry, Jurong, Jiangsu Province, People’s Republic of China. A total of fourteen primiparous purebred Meishan gilts with an average body weight of 36.1 (SEM 1.8) kg were assigned randomly into SP and LP groups. The sows in the SP group were fed diets containing 12 and 14% crude protein, while those in the LP group were fed diets containing 6 and 7% crude protein during gestation and lactation, respectively. The detailed nutritional compositions of these diets are shown in Table 1, and the specific feed formulations can be found in Liang et al. The dietary treatments began before artificial insemination at the first observation of oestrus. Sows were fed twice daily (08.00 and 14.00 hours) and received 1.8 and 2.6 kg/d during gestation and lactation, respectively. Litter size was adjusted to seven to eight pigs per litter at 24 h post-parturition in the same group. Newborn piglets were allowed free access to their mothers and weaned at 35 d of age. One male pig per litter was killed at weaning (35 d). Subcutaneous fat tissues (with vessels and muscles removed) were obtained from the back of the neck within 20 min post-mortem, snap-frozen in liquid N2 and stored at −80°C until further analysis.

All experiments, including feeding, transport, slaughtering and sampling protocols, were undertaken following the guidelines of the Animal Ethics Committee of Nanjing Agricultural University.

RNA isolation

Total RNA was extracted from homogenised adipose tissues using the TRizol Total RNA Kit (Invitrogen Life Technologies) and subsequently purified with the RNase-Free DNase Set (Promega) according to the manufacturer’s instructions. RNA concentration was then quantified by measuring the absorbance at 260 nm in an Eppendorf BioPhotometer (Gene Company Limited). The absorption ratios (260/280 nm) of all preparations were between 1.8 and 2.0. Aliquots of 4 μg RNA were subjected to electrophoresis in a 1.4% agarose–formaldehyde gel to verify sample integrity.

Tissue protein extraction and Western blot analysis

Total protein was extracted from 500 mg of frozen fat tissue in 1 ml lysis buffer (150 mM-NaCl, 10 mM-Tris–HCl, 5 mM-EDTA, 1% Triton X-100 and 0.1% SDS). The protease inhibitor cocktail (Roche Applied Science) was added according to the manufacturer’s instructions. Protein concentration was measured using the Pierce BCA Protein Assay Kit (Thermo Scientific). The protein extract (40 μg) was mixed with loading buffer, denatured by boiling for 5 min and loaded on a 10% SDS-polyacrylamide gel. After electrophoresis, proteins were transferred to nitrocellulose membranes and blocked with 3% bovine serum albumin in 1× Tween-Tris–buffered saline for 90 min at room temperature. After repeated washing with 1× Tween–Tris-buffered saline, the membranes were incubated with the respective antibodies. C/EBP-β was detected using a polyclonal antibody (cs-150X, Santa Cruz Technology) at a dilution of 1:5000. C/EBP-β was detected at approximately 38 kDa. The PPAR-γ antibody (Bioworld Technology) was used at a dilution of 1:500. A protein band at approximately 57 kDa was observed. An antibody against β-actin (Kangcheng, diluted 1:500) was used as internal standard. Goat anti-rabbit IgG peroxidase-conjugated secondary antibodies (Bioworld Technology) were used at a dilution of 1:5000. Finally, the membrane was washed and the specific signals were detected by chemiluminescence using the LumiGlo substrate (SuperSignal West-Pico Trial Kit, Pierce). The C/EBP-β and PPAR-γ contents of the samples are given as the band density values of C/EBP-β and PPAR-γ relative to β-actin. Band densities were analysed with Versa Doc™ 4000 MP (Bio-Rad).
Bioinformatics methods

To assay the deregulation of the miRNA targets of differentially expressed target genes, we used four of the leading miRNA target prediction algorithms: miRanda (http://microrna.sanger.ac.uk/sequences/), PicTar (http://pictar.mdc-berlin.de/)(23), TargetScan (release 5.1, http://www.targetscan.org/)(24) and miRGen (http://www.diana.pcbi.upenn.edu/miRGen.html)(25).

MicroRNA RT-PCR quantification

The RT-PCR analysis of miRNA expression was performed in an Mx3000P system (Stratagene) with specific primers (Table 2). Briefly, total RNA was extracted from adipocytes using the TRIzol reagent (Invitrogen) and subsequently purified with the RNase-Free DNase Kit (Promega) according to the manufacturer’s instructions. Then, miRNA was treated with the Poly(A) Tail Kit (Ambion, AM1350) to add a poly-A tail to the 3′ end of each RNA transcript. The tailing reactions contained 4 µg RNA samples (1 µg/µl), 4 µl of 5X Escherichia coli poly (A) polymerase (E-PAP) buffer, 2 µl of 25 mM-MgCl2, 2 µl of 10 mM-ATP, 0.8 µl E-PAP (2 U/µl) and 2 pmol exogenous control 5 (E5), adjusted to 20 µl with nuclease-free water. The 20 µl reactions were incubated for 1 h at 37°C and held at 4°C. Then, the sample was purified to remove any residual tailing reagents. Complementary DNA were synthesized from the tail RNA using gene-specific primers with oligo-dT (a short sequence of deoxy-thymine nucleotides) adapters. RT reactions contained 2 µg poly-A-tailed miRNA, 1 µg oligo-dT adapter (1 µg/µl) and nuclease-free water. The 10 µl reactions were incubated for 5 min at 70°C (RT1). The RT2 reactions consisted of the entire RT1 reactions, mixed with 5 µl Moloney murine leukaemia virus reverse transcriptase (M-MLV) 5X buffer (containing 250 mM (pH 8.3) Tris–HCl, 15 mM-MgCl2, 375 mM-KCl and 50 mM-dithiothreitol), 1.25 mM of 10 mM-deoxyribonucleotide triphosphate, 1 µM M-MLV RNase (200 U/µl) and 0.5 µl RNase inhibitor (40 U/µl). The 25 µl reactions were incubated at 42°C for 1 h and then at 95°C for 5 min. The 25 µl PCR mixture included 2 µl RT product, 2 µl primers, 8.5 µl sterile 3d H2O and 12.5 µl SYBR Premix Ex Taq TM (TaKaRa). PCR run on an Mx3000P instrument (Agilent Technologies) and analysed using Mx3000P System SDS software (Stratagene).

To evaluate miRNA expression, the E5 small nuclear RNA was used as an exogenous control to normalize the RNA input. E5 is designed as a random sequence and its length is equal to that of the target miRNA (approximately 22 nt); its sequence after synthesis does not yield any matching sequences when blasted to genomic DNA. Furthermore, when the synthesised sequence was used as upstream primer and universal downstream primer to PCR, no Gershgorim band was amplified. The Ct value is defined as the fractional cycle number at which the fluorescence passes the fixed threshold. The fold change was calculated using the 2−ΔΔCt method. All experiments were carried out in triplicate.

Plasmid construction

Pig genomic fragments of miR-130b, miR-374b and precursors of approximately 89 bp (Table 3) were synthesised by Invitrogen. There is only one predicted conserved target site for miR-130b in the entire 3′-untranslated region (UTR) of PPAR-γ (http://www.targetscan.org) and one predicted conserved target site for miR-374b in the entire 3′-UTR of C/EBP-β (http://www.targetscan.org). A 386 bp fragment of the PPAR-γ 3′-UTR was amplified by PCR using the primers 5′-GCTGCTGCAAATATAAAG-3′ and 5′-TAAGGAAGGAAGAGGGAAGG-3′, and a 389 bp fragment of C/EBP-β 3′-UTR was amplified by PCR using the primers 5′-CCACAGTGACTTCGCGGAA-3′ and 5′-CCGACAGACATCTTTAAGCGA-3′. The 386 bp fragment, which contains a broadly conserved motif in the vertebrates for miR-130b (http://www.targetscan.org), and 389 bp fragment, which contains a broadly conserved motif in the vertebrates for miR-374b (http://www.targetscan.org), were cloned downstream of the luciferase gene in the pGL3-Control report luciferase vector (Promega). These constructs, named pGL3-Control/PPAR-γ and pGL3-Control/C/EBP-β, were transfected into HeLa cells. The PCR products were subcloned into the luciferase reporter pGL3-Control using XbaI (Invitrogen). Precursor miR-130b and miR-374b were annealed using annealing buffer (5 X), miRNA precursor

upstream sequence (50 μl) and downstream sequence (50 μl). The 50 μl reaction mixtures were incubated in a ninety-six-well optical plate at 95°C for 2 min, then subjected to touchdown PCR (decrease 0.1°C/8 s till 25°C); the PCR products were subcloned into the pSilencer 3.0-H1 small interfering RNA expression vector using BamHI and Hind III (Invitrogen).

DNA transfection
Approximately 3 × 10⁴/cm² HeLa cells were seeded and cultured in 25 cm² cell culture bottles. When the cells reached 90–95% confluence, they were digested using 0.25% trypsin at 5% CO₂ and 37°C for 2min, then subjected to transformation efficiency), 100 ng pSilence 3.1-H1 neo miR-kinase promotor (pRL-TK) plasmid (used to normalise for fluorescent luciferase reporter plasmid, 10 ng HSV-thymidine kinase promotor (pRL-TK) plasmid or 100 ng luciferase reporter plasmid and 10 ng pRL-TK plasmid. After transfection, the cells were counted. The cell density was approximately 10⁴ cells/cm³. The transfected HeLa cells were incubated at 5% CO₂ and 37°C for 24 and 48 h, respectively.

Dual luciferase activity assay
At 24 and 48 h after transfection, firefly and renilla luciferase activity were measured using a Dual-Luciferase Assay Kit (Promega) with a plate reader (Perkin Elmer). The firefly and renilla luciferase signals were detected using the Veritas Microplate Luminometer (Turner Biosystems). The firefly luciferase activity was compared between miR-130b reporter plasmid and 10 ng pRL-TK plasmid. After transfection, the cells were counted. The cell density was approximately 2 × 10⁴ cells/cm². The transfected HeLa cells were incubated at 5% CO₂ and 37°C for 24 and 48 h, respectively.

SP, standard protein; LP, low protein.
* Mean value was significantly different from that of the SP group (P < 0·05).

Statistical analysis
All data are presented as means with their standard errors. Statistical analyses were carried out with Statistical Program for Social Sciences software 17.0 for Windows (SPSS, Inc.). Differences were tested with ANOVA using a t test for independent samples. P values of less than 0·05 were considered significant.

Results
Offspring body weight and serum NEFA concentration
As shown in Table 2, body weight was significantly lower in the LP groups than the SP groups (P<0·05) at weaning. Moreover, the greatest difference in the back fat thickness (P<0·05) of offspring between the LP and SP groups was detected at the weaning stage (Table 4).

Maternal dietary protein restriction had no significant effect on serum TAG concentrations. Serum NEFA concentration in the LP group was reduced, albeit not significantly (P=0·066), compared with the SP group (Table 4).

PPAR-γ and CCAAT/enhancer-binding protein-β protein expression in subcutaneous fat
The protein expression of PPAR-γ (P<0·05; Fig. 1(a)) was significantly decreased in the subcutaneous fat of offspring pigs at weaning in the LP group compared to the SP group; meanwhile, C/EBP-β protein levels tended to be decreased (P=0·056) in the subcutaneous fat of offspring pigs in the LP group (Fig. 1(b)).
miRNA and effect of maternal dietary protein

Validation of ssc-miR-130b (Sus scrofa miR-130b) targeting PPAR-γ 3′-untranslated region and ssc-miR-374b (Sus scrofa miR-374b) targeting CCAAT/enhancer-binding protein-β 3′-untranslated region

The miR-130b had highly conserved sites for binding to the 3′-UTR of PPAR-γ, and miRNA-374b had highly conserved sites and poorly conserved sites for binding to the 3′-UTR of the C/EBP-β (Fig. 3). To ascertain whether miR-130b is able to recognise the PPAR-γ 3′-UTR or miRNA-374b is able to recognise the C/EBP-β 3′-UTR, we generated a luciferase reporter DNA construct containing the 387 bp pig PPAR-γ 3′-UTR with a putative miR-130b binding site and an ssc-miR-130b overexpression plasmid. The C/EBP-β 3′-UTR and ssc-miR-374b overexpression plasmids were constructed and analysed in the same way. When the pGL3-Control/PPAR-γ 3′-UTR fluorescent luciferase reporter plasmid and miR-130b overexpression vector were cotransfected into HeLa cells, luciferase activity was significantly suppressed by the ectopic expression of miR-130b after cotransfection for 24 or 48h. Similar results were found for the cotransfection of the miR-374b overexpression vector and the luciferase reporter containing the C/EBP-β 3′-UTR (Fig. 4).

Discussion

Many previous studies have demonstrated that maternal protein level during pregnancy and/or lactation can affect the body composition of her offspring later in life(4–6). Consistent with the results of previous studies(26–29), the present study demonstrated a decrease in body weight of offspring subjected to maternal protein restriction during pregnancy and lactation at weaning age. Early life is a critical period for body lipid deposition(30). Previous reports on the effects of maternal protein restriction on plasma parameters are inconsistent. Lucas et al.(51) showed that the offspring of protein-restricted mothers exhibited a long-term reduction in plasma cholesterol, HDL-cholesterol and TAG concentrations compared with controls, whereas Desai et al.(52) Zambrano et al.(52) and Qasem et al.(53) reported that low maternal protein consumption has no significant influence on offspring plasma lipid metabolism indices. In the present study, though the serum NEFA concentration in LP group appeared to be reduced slightly (P=0.066) and the serum TAG levels did not differ significantly between the two groups. Nevertheless, the piglets in the maternal LP group demonstrated significantly decreased subcutaneous fat at the end of the suckling period.

Many transcriptional factors are involved in adipocyte differentiation and lipid metabolism. Previous studies have shown that the overexpression of PPAR-γ can promote fat deposition(34,35). Compared with wild-type mice, PPAR-γ-deficient mice exhibited smaller adipocytes and decreased fat mass(36). Members of the C/EBP family are also important for adipogenesis, and C/EBP-β contributes to the transcriptional activation of PPAR-γ in early adipogenesis(57). In the present study, we found that the miRNA expression of the key transcription factors PPAR-γ and C/EBP-β was not significantly different between the two groups(22). However, when the protein levels of these two genes were measured, the protein level of PPAR-γ was significantly decreased and C/EBP-β was not significantly decreased (P=0.056) in the subcutaneous fat of offspring pigs in the LP group. The incongruity between the miRNA and protein levels hinted that post-transcriptional mechanisms might play a role in regulating these two key lipogenesis factors.

The miRNA are strong post-transcriptional regulators of mammalian differentiation. Recent bioinformatics predictions of miRNA targets in vertebrates demonstrated that hundreds of miRNA are involved in regulating up to 30% of human protein expression levels.
protein-coding genes, though miRNA comprise less than 1% of all predicted genes in human subjects(23,25). Further studies have indicated that miRNA are involved in the regulation of many biological processes, including fat metabolism (8). Although several miRNA have been shown to affect the regulation of adipocyte development, these results have mainly been acquired from cell culture models in vitro (17). The roles of miRNA in adipose tissue, and their maternal effects in particular, are largely unknown. To our knowledge, the present study is the first to report a difference in the expression of miRNA targeting the PPAR-γ and C/EBP-β in the adipose tissue of offspring of mothers fed a LP diet during gestation and lactation.

We identified six candidate PPAR-γ-targeting miRNA by bioinformatics analyses. However, only miRNA-130b expression was significantly different between the LP and SP groups. The miR-130 has been shown to impair adipogenesis upon overexpression by targeting both the coding region

miRNA and effect of maternal dietary protein 1737

When a miR-130b overexpression vector was cotransfected to fully validate the predicted miRNA–mRNA interactions. Luciferase reporter assays were performed to demonstrate that miR-130b and miR-374b may play a role in lipid metabolism. In macrophage and B-cell studies, miR-155 was shown to directly target C/EBP-β, and miR-130 can be expressed in two forms, miR-130a and miR-130b; however, in the present study, only miR-130b expression was significantly up-regulated. Target prediction algorithms identify a single miR-130b binding site in the 3′ UTR of PPAR-γ, and the 3′ UTR is highly conserved among mammals. Luciferase reporter assays were performed to fully validate the predicted miRNA–mRNA interactions. When a miR-130b overexpression vector was cotransfected into HEK293 cells with a luciferase reporter vector containing PPAR-γ 3′-UTR, luciferase activity was significantly suppressed. These results confirmed that miR-130b directly recognises and binds to the 3′-UTR of PPAR-γ, thereby suppressing PPAR-γ gene expression. In a previous study, miR-27 was shown to repress PPAR-γ in human multi-potent adipose-derived stem cells. However, in the present study, neither miR-27a nor miR-27b demonstrated a significant difference between the two groups.

Among the miRNA related to C/EBP-β, miR-378/378c and miR-143 are known to influence C/EBP-β transcriptional activity. In macrophage and B-cell studies, miR-155 was shown to directly target C/EBP-β. The present study demonstrates for the first time that miR-374b expression is significantly different between the SP and LP groups. The miRNA-374 expression has been reported to vary in association with lung cancer. Furthermore, in the present study, miR-374b overexpression was able to reduce the activity of a luciferase reporter containing the C/EBP-β 3′-UTR after cotransfection for 24 or 48 h. These results indicate that miR-374b can directly recognise and bind to the 3′-UTR of C/EBP-β and suppress C/EBP-β expression.

In contrast, miR-130b did not alter the activity of a luciferase reporter that has no PPAR-γ 3′-UTR, and miR-374b did not alter the activity of a luciferase reporter that has no C/EBP-β 3′-UTR (data not shown). These results imply that inhibitory effects of miR-130b on PPAR-γ expression and miR-374b on C/EBP-β expression are quite selective, as suggested by bioinformatics analyses. The present results indicate that miRNA-130b and miR-374b are likely to interact with the 3′-UTR of PPAR-γ and C/EBP-β, respectively, and consequently down-regulate their expression at the post-transcriptional level. In addition, there are two predicted miR-374b binding sites in the C/EBP-β 3′-UTR. One is a conserved binding site between positions 484 and 490, and the other site is a poorly conserved motif between positions 154 and 160. In the present study, we focused on the highly conserved binding site for the validation of miR-374b.

In conclusion, the present data represent the first description of the post-transcriptional regulation of lipid metabolism in the weaning-age offspring of female pigs fed a LP diet. Among several predicted miRNA tested, we provide evidence that miR-130b and miR-374b may play a role in lipid metabolism regulation. Anyway, every miRNA is thought to regulate an average of approximately 200 target genes and have widespread effects. A complete understanding of the biological functions of miR-130b and miR-374b in lipid metabolism requires further studies.

Acknowledgements

The present study was supported by the National Basic Research Program of China (2012CB124703), the Special Fund for Agro-scientific Research in the Public Interest (201003011), the Major National Science and Technology Projects of China (2009ZX08009-138B) and the Priority Academic Program Development of Jiangsu Higher Education Institutions. X. Y. and R. Z. designed the study; S. P. and Y. Z. performed the experiments; S. P. and X. Y. analysed the data and wrote the paper. The authors declare that there is no conflict of interest.
