Unrecognised psychopathology in patients with difficult asthma: major mental and personality disorders

Lonneke C.J. Prins, Maarten J.M. van Son, Anton R.J. van Keimpema, Jan-Willem G. Meijer, Martina E.F. Bühring and Victor J.M. Pop

Background
Difficult asthma is a severe subgroup of asthma in which the main feature is uncontrollability of symptoms. Psychopathology is suggested to be prominent in patients with difficult asthma and considered important in its treatment; however, the evidence is scarce.

Aims
To describe psychopathology in difficult asthma, both major mental and personality disorders, based on diagnostic interviews.

Method
This study was conducted in a specialised asthma care centre. A total of 51 patients with difficult asthma were diagnosed at the start of the treatment programme using two structured clinical interviews for both major mental (SCID-I) and personality disorders (SCID-II) according to DSM-IV-TR.

Results
About 55% of the patients with difficult asthma had a psychiatric disorder of which 89% was undiagnosed and untreated before being interviewed. About 49% had a minimum of one major mental disorder of which the cluster of anxiety disorders was the most common cluster of major mental disorders, followed by somatoform disorders. About 20% were diagnosed with a personality disorder. Of the 10 patients with a personality disorder, 9 had an obsessive-compulsive personality disorder.

Conclusions
This study demonstrates that more than half of patients with difficult asthma had a psychiatric disorder of which 89% was unrecognised. This study highlights the importance of offering patients with difficult asthma a psychiatric diagnostic interview and/or a psychiatric consultation as part of their routine medical examination and provision of appropriate psychiatric treatment. Moreover, it highlights the urgency of further research into the role of psychopathology in the development of difficult asthma.

Asthma is a lifelong respiratory disease characterised by airway obstruction, airway inflammation and bronchial hyperresponsiveness. Asthma is a global health problem, which affects about 1 in 12 people in the USA (8% of 316 million, 25 million) and numbers are increasing every year. International guidelines on the treatment of asthma advocate a stepwise approach (Global Initiative for Asthma, GINA). This stepwise approach consists mainly of five steps of pharmacological treatment, the final step including systemic corticosteroids (apart from general recommendations of avoiding asthma triggers, adequate drug compliance, etc.). In most asthmatic patients, the occurrence of symptoms and/or asthma attacks can be controlled with the GINA approach. However, there is a subcategory of asthmatic patients who cannot control their symptoms despite treatment at step 4 or 5 of the GINA guidelines. In clinical practice, these patients are defined as those who present with difficult asthma, affecting approximately 5% of the asthmatic population. This would mean that about 1.25 million people in the USA and 2.5 million in Europe suffer from difficult asthma.

Difficult asthma has a profound impact on health status and quality of life. Patients with difficult asthma have frequent exacerbations that can result in hospitalisations, emergency room visits and days of absence from work or school. Moreover, patients with difficult asthma have an increased risk of sudden asthma death and adverse effects of high-dose corticosteroids. Although the interest in difficult asthma has grown considerably, the aetiology of difficult asthma is poorly understood. It is well known that major mental disorders are highly prevalent (31%) in asthma patients in general compared with the general population (26%). This 31%, however, encompassed both patients with treatable asthma and difficult asthma, which leaves the question whether the higher prevalence could be attributed to patients with asthma in general or to the difficult asthma population specifically. The prevalence of major mental disorders in difficult asthma appears to be high, but is hardly studied. Two studies by Heaney and colleagues showed a prevalence of 49% in difficult asthma. However, these studies did not use structured interviews and used ICD-10 criteria instead of the DSM-IV-TR criteria for assessing mental and personality disorders. These studies did report 81.3% of mental disorders to be unrecognised. Although there is a recent publication on personality traits in difficult asthma, to the best of our knowledge the prevalence of personality disorders in difficult asthma has not been previously reported utilising systematic research diagnostic interviews.

Therefore, the current study assessed the prevalence of psychopathology in difficult asthma focusing on both major mental and personality disorders using research diagnostic interviews according to the DSM-IV-TR.

Method
This study was conducted in Asthma Centre Heideheuvel, Hilversum, The Netherlands, a specialised asthma care centre.
that offers in-patient pulmonary rehabilitation. Asthmatic patients referred to in-patient rehabilitation have highly impaired health status and no satisfactory response to prior medical and non-medical treatment by asthma specialists, often including out-patient rehabilitation. Patients enter the rehabilitation centre only after a multidisciplinary assessment of four days, confirming their indication. Patients have to be abstinent from smoking.

Participants
During a period of 17 months, 65 patients with difficult asthma entered the treatment programme and were invited to participate in the current study. This included, apart from the standard intake programme, a psychiatric interview. Seven patients did not give informed consent and another seven patients dropped out during the intake of the rehabilitation programme before diagnostic interviews were performed. The remaining 51 patients consented to participate. Their characteristics are shown in Table 1.

Measurements
In the first weeks after the start of the programme, each patient was interviewed by trained psychologists with the structured clinical interview (SCID-I) diagnosing major mental disorders and the structured clinical interview (SCID-II) diagnosing personality disorders, both according to DSM-IV-TR.

Ethical principles
Both the institutional medical ethics committee of the Asthma Centre and the medical ethics committee of the Utrecht Medical Centre approved the study protocol according to Dutch law. Patients were sent information about the study before they agreed on participation. All patients gave written informed consent.

Statistical methods
Statistical analysis was performed using SPSS Statistics for Windows Version 19.0. To determine characteristics and psychopathology of the participants, descriptive statistics were used. Associations between subgroups of patients were analysed using chi-square statistics.

Results
The characteristics of the 51 patients with difficult asthma are shown in Table 1. Of these, 41 patients (80.4%) were female, 45.1% were obese, 47.1% had a medium educational level and 84.3% middle-class SES. Of the 51 patients with difficult asthma, 28 patients (54.9%) had one or more major mental and/or personality disorders (Table 2). Females were more likely to have a major mental disorder (58.5%) compared with male patients (29.9%).

| NOS, not otherwise specified. a. Patients may have more than one major mental and/or psychiatric disorder.

Of the 28 patients who were diagnosed with a psychiatric disorder, 3 patients had a psychiatric diagnosis before referral to the rehabilitation centre; one had an obsessive-compulsive personality disorder (receiving psychotherapy), one had a somatisation disorder (receiving psychotherapy) and one patient had a major depressive disorder (using antidepressants). This means that 25 of the 28 (89.3%) patients had a psychiatric diagnosis.
which was not diagnosed before. Of the 23 patients who were not
diagnosed with a psychiatric disorder according to the structured
interviews, one patient received antidepressants and another six
patients received benzodiazepines for sleeping problems (all
prescribed by their GP).

Discussion
This is one of the first studies in patients with difficult asthma
assessing psychopathology using the DSM-IV-TR criteria. The
strength of the current study is the involvement of structured
interviews (SCID-I and SCID-II) in order to get a DSM-IV-TR
classification. The current study showed that over half (54.9%) of
the patients with difficult asthma referred to the specialised
asthma care centre had one or more psychiatric disorders
(89.3% of which were previously unrecognised). Specifically, 49% of
all patients had a major mental disorder and 19.6% were
diagnosed with a personality disorder. Heaney et al.11,12 reported a
similar prevalence (49%) of major mental disorder in patients with
difficult asthma of which 81.3% was unrecognised. However, this
study did not use structured interviews and diagnosed according
to ICD-10 criteria. This prevalence is higher in comparison to the
study who received a psychiatric diagnosis were not diagnosed
before. Because of the dramatic manifestation of difficult asthma,
psychiatric symptoms like anxiety or panic can be mistaken for
asthma symptoms, which might explain the high number of
unrecognised psychiatric disorders. Moreover, stigma about psychia-
tric disorders, for instance, resulting in being afraid that a psychiatric
disorder would negatively impact asthma treatment, could cause
unwillingness to acknowledge and accept psychiatric symptoms.11

Although beyond the scope of the current study, an important
question about the direction of the relation is: is psychopathology
a contributor or a consequence of difficult asthma? Psychiatric
symptoms could worsen asthma symptoms and the dramatic
manifestation of asthma symptoms in difficult asthma could
probably cause or worsen psychiatric symptoms. However, the
impact of psychiatric symptoms on difficult asthma does not
appear to be a straightforward one.11 Moreover, because by
definition, most patients with difficult asthma use corticosteroids
and it is well known that these drugs have major psychotrophic
side-effects, a possible independent effect of this medication on
major mental disorders should be taken into account.26 Psycholog-
ical distress is heightened in patients with severe prednisone-
dependent asthma14 and the use of oral corticosteroids are related
to lower quality of life.27 Several psychiatric disorders are
significantly associated with adult-onset asthma.28 Prospective
research is needed in which patients who develop difficult asthma
after a prior diagnosis of asthma are followed and for patients with
a first diagnosis of a psychiatric disorder and with a first diagnosis
of asthma, to elucidate on a possible contributing role of
psychiatric disorder in difficult asthma.

Both major mental disorders and personality disorders29 have
a substantial impact on quality of life, which is known to be poor
in patients with difficult asthma.30 Based on the effect of
psychiatric therapy in general,21 it is reasonable to suggest that
the treatment of major mental and personality disorders also
improves quality of life in difficult asthma. In chronic obstructive
pulmonary disease (COPD), a severe pulmonary disease in which
also high doses of corticosteroids are used, comparable figures of
psychiatric disorder are reported.31 In this population, the risk of
missing diagnoses and treatment of concurrent psychiatric
disorder is also high.32 Studies on the treatment of psychiatric
disorder in COPD show improvement for both physical and
psychiatric complaints.32 Given these results, one might hypothe-
sise that similar outcomes of treatment might be obtained in a
difficult asthma population. Future research is needed to deter-
mine the benefit of psychotherapy and/or pharmacotherapy in
standard difficult asthma treatment.

This study advocates the importance of offering patients
with difficult asthma a psychiatric diagnostic interview and/or a
psychiatric consultation as part of their general medical examina-
tion since 54.9% of patients with difficult asthma were diagnosed
with a psychiatric disorder, most of them unrecognised and
untreated. Furthermore, the results stress the urgency of further
research into the potential roles of mental disorders in difficult
asthma and of difficult asthma in mental disorders.
