# Asymptotic Formulae for the Lattice Point Enumerator 

U. Betke and K. Böröczky, Jr.

Abstract. Let M be a convex body such that the boundary has positive curvature. Then by a well developed theory dating back to Landau and Hlawka for large $\lambda$ the number of lattice points in $\lambda M$ is given by $G(\lambda M)=$ $V(\lambda M)+O\left(\lambda^{d-1-\varepsilon(d)}\right)$ for some positive $\varepsilon(d)$. Here we give for general convex bodies the weaker estimate

$$
|G(\lambda M)-V(\lambda M)| \leq \frac{1}{2} S_{Z^{d}}(M) \lambda^{d-1}+o\left(\lambda^{d-1}\right)
$$

where $S_{Z^{d}}(M)$ denotes the lattice surface area of $M$. The term $S_{Z^{d}}(M)$ is optimal for all convex bodies and $o\left(\lambda^{d-1}\right)$ cannot be improved in general. We prove that the same estimate even holds if we allow small deformations of $M$.

Further we deal with families $\left\{\mathrm{P}_{\lambda}\right\}$ of convex bodies where the only condition is that the inradius tends to infinity. Here we have

$$
\left|G\left(P_{\lambda}\right)-V\left(P_{\lambda}\right)\right| \leq d V\left(P_{\lambda}, K ; 1\right)+o\left(S\left(P_{\lambda}\right)\right)
$$

where the convex body $K$ satisfies some simple condition, $V\left(P_{\lambda}, K ; 1\right)$ is some mixed volume and $S\left(P_{\lambda}\right)$ is the surface area of $\mathrm{P}_{\lambda}$.

## 1 Introduction

As we work with concepts from convex geometry and the geometry of numbers, our notation is taken from the standard books [S], [GL]. M ore specifically we denote by Ed the $d$-dimensional Euclidean space with norm $\|\cdot\|$ and by $\mathcal{K}^{d}$ the family of all convex bodies with non-empty interior in $E^{d}$. We write $\Lambda$ for a lattice in $E^{d}, \Lambda^{*}$ for its dual lattice, i.e.,

$$
\Lambda^{*}=\{v \mid\langle v, u\rangle \in \mathrm{Z} \text { for } \mathrm{u} \in \Lambda\}
$$

We note that the primitive vectors of $\Lambda^{*}$ are normals to the lattice hyperplanes of $\Lambda$. We denote the determinant of $\Lambda$ by det $\Lambda$ and the lattice point enumerator of a set $M \subset \mathrm{E}^{\mathrm{d}}$ by $G_{\Lambda}$, i.e., $G_{\Lambda}(M)=\#(\Lambda \cap M)$. In the special case $\Lambda=Z^{d}$ we frequently write $G(M)$ rather than $G_{Z^{d}}(M)$. For a set $M \subset E^{d}$ we write $\partial M$ for its boundary, $c l M$ for its closure, int $M$ for its interior, relint $M$ for its relative interior (interior with respect to its affine hull), and $\operatorname{dim} M$ for its affine dimension.

We are interested in the so called "circle problem"; namely, to determine $G_{\Lambda}(\lambda M)$ for $M \in \mathcal{K}^{d}$ and large real $\lambda$. For the unit ball $B^{d}$ this is a well known problem in the theory of

[^0]numbers which goes back to Gauss. For the more general case that M has positive curvature, $\mathrm{G}(\lambda \mathrm{M})$ is estimated by the following formula which goes back to Landau and Hlawka (see [GL]), and was recently improved by Krätzel and Nowak ([KN ]):
\[

$$
\begin{equation*}
G_{\Lambda}(\lambda M)=\frac{V(M)}{\operatorname{det} \Lambda} \cdot \lambda^{d}+0\left(\lambda^{d-2+3 /(2 d)}(\log \lambda)^{2 / d}\right) . \tag{1}
\end{equation*}
$$

\]

Clearly (1) does not hold anymore if $M$ contains a facet parallel to some lattice ( $d-1$ )plane as then the error term can be no better than $O\left(\lambda^{d-1}\right)$. Some more insight in the nature of the error term is given by Ehrhart's formula for the number of lattice points in lattice polytopes (see again [GL]). To state Ehrhart's result we need some more notation.

For a non-zero vector $u$ and $M \in \mathcal{K}^{d}$ we write $u^{\perp}$ for the linear ( $d-1$ )-space orthogonal to $u$ and $F_{M}(u)$ for the face of $M$ with outer normal vector $u$. In addition, $\mathcal{H}^{-k}$ denotes the k-dimensional Hausdorff-measure normalized so that it coincides with the $k$-dimensional Lebesgue-measure along hyperplanes. In particular, the surface-area $\mathcal{H}^{d-1}(\partial \mathrm{M})$ of M is denoted by $S(M)$.

For $M \in \mathcal{K}^{d}$ the "lattice surface area" $S_{\Lambda}(M)$ with respect to $\Lambda$ is defined by

$$
S_{\Lambda}(M)=\sum_{v \in \Lambda^{*} \text { primitive }} \frac{\mathcal{H}^{d-1}\left(F_{M}(v)\right)}{\operatorname{det}\left(v^{\perp} \cap \Lambda\right)} .
$$

Now Ehrhart's formulae (see $[G L]$ ) for $G_{\Lambda}(\lambda P)$ for a lattice polytope $P$ and natural $\lambda$ make the role of $S_{\Lambda}(P)$ more transparent:

$$
\begin{align*}
G_{\Lambda}(\lambda P) & =\sum_{i=0}^{d} G_{i}(P) \lambda^{i},  \tag{2}\\
G_{\Lambda}(\operatorname{int}(\lambda P)) & =\sum_{i=0}^{d}(-1)^{d-i} G_{i}(P) \lambda^{i} \tag{3}
\end{align*}
$$

where $G_{d}(P)=V(P) / \operatorname{det} \Lambda, G_{d-1}(P)=\frac{1}{2} S_{\Lambda}(P)$ and $G_{0}(P)=1$, while the remaining $G_{i}$ have a less obvious meaning (see [DR]).

Ehrhart's formula can easily be turned into an estimate of $\mathrm{G}_{\lambda}$ for all $\lambda>0$ for a slightly more general class than lattice polytopes. For the sake of a better name we say that a polytope $P$ is a lattice facet polytope if for every facet some normal of the facet is in $\Lambda^{*}$, or in other words the hyperplanes spanned by the facets of $P$ are parallel to lattice-hyperplanes of $\Lambda$.

Theorem A Let $\Lambda$ be a lattice in $E^{d}$ and $P$ bea lattice-facet polytope. Then

$$
\left|\frac{V(\lambda P)}{\operatorname{det} \Lambda}-G_{\Lambda}(\lambda P)\right| \leq \frac{1}{2} S_{\Lambda}(P) \lambda^{d-1}+O\left(\lambda^{d-2}\right) .
$$

Ehrhart's formulae (2), (3) show that the estimate in Theorem A including the error term is optimal.

In fact the main result of our paper is a generalization of this result to general convex bodies which additionally allows some deformation of the shape of $M$.
Theorem B Let $\Lambda$ be a lattice in $E^{d}$ and $M \in \mathcal{K}^{d}$. If a family $\left\{Q_{\lambda}\right\}$ of convex bodies tends to M as $\lambda \rightarrow \infty$ then

$$
\left|\frac{\mathrm{V}\left(\lambda Q_{\lambda}\right)}{\operatorname{det} \Lambda}-\mathrm{G}_{\Lambda}\left(\lambda \mathrm{Q}_{\lambda}\right)\right| \leq \frac{1}{2} S_{\Lambda}(\mathrm{M}) \lambda^{\mathrm{d}-1}+o\left(\lambda^{\mathrm{d}-1}\right)
$$

At this point it seems worth while to mention that there is an application of Theorem $B$ (and Theorem D below) to calculate the densities of large finitelattice packings (see [ABB], [BB]). If $d=2$ then Theorem $B$ is a trivial consequence of Pick's formula (this celebrated formula can be found in e.g. [GL]).

We notethat for $M=Q_{\lambda}$, Theorem $B$ becomes
Corollary C For $M \in \mathcal{K}^{d}$,

$$
\left|\frac{V(\lambda M)}{\operatorname{det} \Lambda}-G_{\Lambda}(\lambda M)\right| \leq \frac{1}{2} S_{\Lambda}(M) \lambda^{d-1}+o\left(\lambda^{d-1}\right)
$$

We remark that the same estimate holds if we consider arbitrary translates of $\lambda M$.
If $M$ is strictly convex then $S_{\Lambda}(M)=0$, and hence

$$
\operatorname{det} \Lambda \cdot G_{\Lambda}(\lambda M)=V(\lambda M)+0(S(\lambda M))
$$

In view of the formula of Landau and Hlawka and Theorem A, the error term in Theorem B and particularly in Corollary C appears to be very weak, but in fact it is best possible as a series of examples in Section 6 will show.

For the next theorem we consider a more general family $\mathrm{P}_{\lambda} \in \mathcal{K}^{d}, \lambda \in \mathrm{~N}$, such that for theinradiusr we haver $\left(P_{\lambda}\right) \rightarrow \infty$. Weprove a bound for thelattice point enumerator with the help of a suitable mixed volume.

Again we need some more notation. Let $\mathrm{M}, \mathrm{K} \in \mathcal{K}^{\mathrm{d}}$ and let $\mathrm{H}_{\mathrm{K}}(\cdot)$ denote the support function of $K$. Then $V(\lambda M+K)$ is a polynomial in $\lambda$; namely,

$$
V(\lambda M+K)=\sum_{i=0}^{d}\binom{d}{i} V(M, K ; i) \lambda^{d-i}
$$

(see[S]). We are interested in the term $V(M, K ; 1)$. It is well known that

$$
\begin{equation*}
V(M, K ; 1)=\frac{1}{d} \cdot \int_{\partial M} H_{K}\left(n_{x}\right) d \mathcal{H}^{d-1}(x) \tag{4}
\end{equation*}
$$

where $n_{x}$ is an exterior unit normal at $x \in \partial M$. We note that $n_{x}$ is unique almost $\mathcal{H}^{d-1}$ everywhere on $\partial \mathrm{M}$. For a polytope M , (4) becomes simply

$$
\begin{equation*}
V(M, K ; 1)=\frac{1}{d} \cdot \sum_{u \in S^{d-1}} H_{K}(u) \cdot \mathcal{H}^{d-1}\left(F_{M}(u)\right) \tag{5}
\end{equation*}
$$

where $\mathcal{H}^{d-1}\left(\mathrm{~F}_{\mathrm{M}}(\mathrm{u})\right) \neq 0$ only if u is the exterior normal to a facet of M . Thenormalization reflects the definition of mixed volumes (see [S]).

After these preparations, we state our next
Theorem $\mathbf{D}$ Let $\Lambda$ be a lattice in $E^{d}$ and assume that for some $K \in \mathcal{K}^{d}, H_{K}(v) \geq 1 / 2$ for any primitive $v \in \Lambda^{*}$. If $\left\{P_{\lambda}\right\}$ is a family of convex bodies with $r_{d}\left(P_{\lambda}\right) \rightarrow \infty$ as $\lambda \rightarrow \infty$ then

$$
\left|\mathrm{V}\left(\mathrm{P}_{\lambda}\right)-\operatorname{det} \Lambda \cdot \mathrm{G}_{\Lambda}\left(\mathrm{P}_{\lambda}\right)\right| \leq \mathrm{dV}\left(\mathrm{P}_{\lambda}, \mathrm{K} ; 1\right)+0\left(\mathrm{~S}\left(\mathrm{P}_{\lambda}\right)\right) .
$$

The condition on $H_{K}(v)$ makes sure that $K$ is sufficiently large with respect to $\Lambda$ : For $\mathrm{v} \in \Lambda^{*}$ primitive and $\mathrm{u} \in \Lambda$ with $\langle\mathrm{u}, \mathrm{v}\rangle=1$ we have that $\mathrm{H}_{\mathrm{K}}(\mathrm{v}) \geq 1$ is equivalent to saying that $K$ intersects $u+\operatorname{lin}\left(v^{\perp} \cap \Lambda\right)$, which is the closest non-linear affine lattice hyperplane to the origin normal to v .

While our work deals with large bodies we should remark that for the special case of $Z^{d}$ there are estimates for $G(M)-V(M)$ for all bodies. A survey on these results can be found in [BW]. Especially a somewhat related lower bound was given in [BHW ]; namely, $G_{Z^{d}}(M) \geq V(M)-\frac{1}{2} S(M)$.

We proceed as follows: Sections 2, 3 and 4 provide the auxiliary statements which we need for the proofs of Theorem B and Theorem D. In Section 5 we start with a proof of Theorem A. While the statement of this theorem is folklore, we are not aware of a written proof. Furthermore the ideas of the proof are the same as in the rather more complicated Theorem B. Thus we use the proof of Theorem A as an outline of the proof of Theorem B and it might be useful to start to read the paper at that point. In Section 6, we discuss the exactness of the estimates in Theorem B. Finally Section 7 is devoted to the proof of Theorem D.

## 2 Approximation of Convex Bodies

In Sections 2 and 3, we discuss some elementary metrical properties of convex surfaces. The standard reference book for this and the next section is [S]. For the basic properties of H ausdorff measure, consult any monograph on geometric measure theory, for example the classical book [F].

The Euclidean distance function is denoted by $\delta(\cdot, \cdot)$ and $\Delta^{H}(\cdot, \cdot)$ stands for the H ausdorff distance of compact sets. We denote by $\angle(u, v)$ the angle of the vectors $u$ and $v$. For $\sigma \subset \mathrm{E}^{\mathrm{d}}$ and $\omega \geq 0, \mathrm{~N}(\sigma, \omega)$ is the set of points with distance less than $\omega$ from $\sigma$.

Let $M$ be some convex body containing 0 in its interior. Then for $x \neq 0$, the radial projection $\pi_{\partial \mathrm{M}}(\mathrm{x})$ of x into $\partial \mathrm{M}$ is well defined.

For the rest of the section we consider an $M \in \mathcal{K}^{d}$ such that for some positive $r$ and $R$, $r B^{d} \subset \operatorname{int} M$ and $M \subset \operatorname{intRB}{ }^{d}$.

Lemmas 2.1, 2.2 and 2.3 are easy consequences of the fact that for a convergent sequence of convex bodies, supporting hyperplanes can converge only to some supporting hyperplane of the limit.

Lemma 2.1 Let $\Pi \subset \partial \mathrm{M}$ have the property that for $\mathrm{x}, \mathrm{y} \in \mathrm{cl} \Pi$ and all $\mathrm{n}_{\mathrm{x}}$ and $\mathrm{n}_{\mathrm{y}}$, $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}\right)<\alpha$ holds. Then there exists a positive $\omega$ with the following property: Let $\mathrm{Q} \in \mathcal{K}^{\mathrm{d}}$ with $\Delta^{H}(Q, M)<\omega$ and $u, v \in \pi_{\partial Q}(\Pi)$. Then $\angle\left(n_{u}, n_{v}\right)<2 \alpha$ holds.

For any set $\sigma \subset \mathrm{S}^{\mathrm{d}-1}$ and convex body P we denote by $\psi_{\mathrm{P}}(\sigma)$ the subset of $\partial \mathrm{P}$ whose points have an outer normal contained in $\sigma$.

Lemma 2.2 Let $u \in S^{d-1}$. For positive $\theta$ there exist positive $\alpha$ and $\omega$ such that if $\Delta^{H}(\mathrm{M}, \mathrm{Q})<\omega$ then $\psi_{Q}\left(\mathrm{~S}^{d-1} \cap N(u, \alpha)\right)$ is a subset of the radial projection of $\partial \mathrm{M} \cap$ $\mathrm{N}\left(\psi_{\mathrm{M}}(\mathrm{u}), \theta\right)$ onto $\partial \mathrm{Q}$.

For $\mathrm{F} \in \mathscr{K}^{d}$ we denote by $\mathrm{r}(\mathrm{F})$ the relative inradius of F , i.e., the radius of the largest ball with the same dimension as $F$ that is contained in $F$. Then for $0 \leq \theta \leq r(F)$ we write $\mathrm{F}_{-\theta}$ for the subset of F whose points are at least distance $\theta$ from each point of the relative boundary $\partial \mathrm{F}$ of F ("inner parallel body").

Lemma 2.3 Let $\mathrm{F}=\mathrm{F}_{\mathrm{M}}(\mathrm{u})$ such that $\operatorname{dim} \mathrm{F}=\mathrm{d}-1$ for some $\mathrm{u} \in \mathrm{S}^{\mathrm{d}-1}$ and $0<\theta<\mathrm{r}(\mathrm{F})$. Then for any $\alpha>0$ there exists an $\omega>0$ with the following property: If $\mathrm{Q} \in \mathcal{K}^{d}$ such that $\Delta^{H}(\mathrm{Q}, \mathrm{M})<\omega$ and $\mathrm{x} \in \pi_{\partial \mathrm{Q}}\left(\mathrm{F}_{-\theta}\right)$ then $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{u}\right)<\alpha$ for any normal vector $\mathrm{n}_{\mathrm{x}}$ at x to Q .

In order to compute $\mathrm{G}_{\mathrm{z}^{\mathrm{d}}}(\mathrm{M})-\mathrm{V}(\mathrm{M})$ we introduce some more notation. For $\mathrm{z}=$ $\left(z_{1}, \ldots, z_{d}\right) \in Z^{d}$ we denote by $W(z)$ the unit cubeW $(z)=\left\{\left(x_{1}, \ldots, x_{d}\right) \left\lvert\,-\frac{1}{2} \leq z_{i}-x_{i}<\right.\right.$ $\left.\frac{1}{2}, i=1, \ldots, d\right\}$. For a closed convex set Q let $\mathrm{z}_{\alpha}=\left(\mathrm{z}_{1}, \ldots, \mathrm{z}_{\mathrm{i}-1}, \mathrm{z}_{\mathrm{i}}+\alpha, \mathrm{z}_{\mathrm{i}+1}, \ldots, \mathrm{z}_{\mathrm{d}}\right) \in \partial \mathrm{Q}$ with $\mathrm{z}_{\mathrm{i}} \in \mathrm{Z}, \mathrm{i}=1, \ldots, \mathrm{~d}$ and $-\frac{1}{2} \leq \alpha<\frac{1}{2}$ such that $\left\langle\mathrm{n}_{\mathrm{z}_{\alpha}}, \mathrm{e}\right\rangle>0$ ( e , is the i -th coordinate unit vector). Then the i -tower Z of Q at $\mathrm{z}_{\alpha}$ is the union of all cubes $\mathrm{W}(\bar{z})$ with $\bar{z}=\left(z_{1}, \ldots, z_{i-1}, \bar{z}_{i}, z_{i+1}, \ldots, z_{d}\right)$ such that there is an $x \in W(\bar{z}) \cap \partial Q$ with $\left\langle n_{x}, e_{i}\right\rangle>0$. For $\left\langle\mathrm{n}_{z^{*}}, \mathrm{e}\right\rangle<0$ the $i$-tower Z is defined correspondingly. If for all lattice points $Z \in Z$ the points $x \in W(z) \cap \partial Q$ are in a common facet of $Q$ then we obviously have

$$
\sum_{z \in Z, z \in Q} V(W(z) \backslash Q)-\sum_{z \in Z, z \notin Q} V(W(z) \cap Q)= \begin{cases}\frac{1}{2}-\alpha & \text { for } \alpha \geq 0 \\ -\frac{1}{2}-\alpha & \text { for } \alpha<0\end{cases}
$$

Thus for an $i$-tower $Z$ at $z_{\alpha}$ we define the deviation $\operatorname{dev} Z$ of $Z$ by

$$
\operatorname{dev} Z=\left|\sum_{z \in Z, z \in Q} \mathrm{~V}(W(z) \backslash Q)-\sum_{z \in Z, z \notin Q} \mathrm{~V}(W(z) \cap Q)-\frac{1}{2}+\alpha\right|
$$

for $\alpha \geq 0$ and

$$
\operatorname{dev} Z=\left|\sum_{z \in Z, z \in Q} \mathrm{~V}(\mathrm{~W}(\mathrm{z}) \backslash \mathrm{Q})-\sum_{\mathrm{z} \in \mathrm{Z}, \mathrm{z} \notin \mathrm{Q}} \mathrm{~V}(\mathrm{~W}(\mathrm{z}) \cap \mathrm{Q})+\frac{1}{2}+\alpha\right|
$$

for $\alpha<0$.
Lemma 2.4 Let $z_{\alpha}=\left(z_{1}, z_{2}, \ldots, z_{i}+\alpha, \ldots, z_{d}\right) \in \partial Q$ with $\mathrm{z}_{\mathrm{i}} \in \mathbf{Z}$ for $\mathrm{i}=1, \ldots, \mathrm{~d}$ and $-\frac{1}{2} \leq \alpha<\frac{1}{2}$, and $\mathrm{n} \in \mathrm{S}^{\mathrm{d}-1}$ with $\langle\mathrm{e}, \mathrm{n}\rangle \geq \beta$ for $\beta>0$. Let H denote the plane through $\mathrm{z}_{\alpha}$ with normal n . Then for every $\varepsilon>0$ there exists a $\gamma>0$ depending only on $\beta$ and $\varepsilon$ with the following property: Let $Z$ be the $i$-tower at $\mathbf{z}_{\alpha}$. If $\angle\left(\mathrm{n}, \mathrm{n}_{\mathrm{x}}\right) \leq \gamma$ holds for every $\mathrm{x} \in \mathrm{Z} \cap \partial \mathbf{Q}$ then
(a) $\operatorname{dev} Z<\varepsilon$.
(b) $\left|\mathcal{H}^{\mathrm{d}-1}(\mathrm{H} \cap \mathrm{Z})-\mathcal{H}^{\mathrm{d}-1}(\partial \mathrm{Q} \cap \mathrm{Z})\right|<\varepsilon$.

The next lemma gives bounds for the angles between sections of certain planes:
Lemma 2.5 Let H be a hyperplane with normal n and E be a two-dimensional plane spanned by the vectors $\mathrm{u}_{1}, \mathrm{u}_{2}$ such that $\angle\left(\mathrm{n}, \mathrm{u}_{1}\right) \leq \gamma<\pi / 2$. Then for every $\xi>0$ exists an $\eta>0$ depending only on $\gamma, \xi$ such that for any hyperplane $\mathrm{H}_{1}$ with normal $\mathrm{n}_{1}$ and $\angle\left(\mathrm{n}_{1}, \mathrm{n}\right) \leq \eta$ we have $\angle\left((\mathrm{E} \cap \mathrm{H}),\left(\mathrm{E} \cap \mathrm{H}_{1}\right)\right) \leq \xi$.

In the last section we have to deal with convex bodies, whose extension in some directions is much larger than their extension in other directions. This situation is conveniently described by means of different inradii and best approximating planes: For $K \in \mathcal{K}^{d}$ we denote the $k$-th inradius, that is the radius of the largest $k$-dimensional ball contained in $K$ by $r_{k}$. For every $k$-plane $L$ exists an $\omega(L)$ for which $K \subset L+\omega(L) B^{d}$. Now the best approximating $k$-plane $L^{k}(K)$ is the plane $L$ for which $\omega(\mathrm{L})$ becomes minimal. There is a well-known connection between radii and best approximating planes (see [P]):

$$
\begin{equation*}
K \subset L^{k}(K)+(k+2) r_{k+1}(K) B^{d} . \tag{6}
\end{equation*}
$$

As we frequently need to consider orthogonal projections of sets onto planes we write $\pi_{\mathrm{L}}(\mathrm{M})$ for the orthogonal projection of the set M onto the planeL. Further wewrite $\mathrm{L}^{\perp}$ for the complementary orthogonal linear plane of $L$.

For someestimates we use a different notion of $k$-inradius, which was discussed in [BH ]: Thek-th inradius $r_{k}^{\pi}(K)$ with respect to projection is the radius of the largest $k$-ball, which is contained in a projection of $K$ onto a k -dimensional plane. Of course the two notions of $k$-inradius are not independent:

Lemma 2.6 Let $K \in \mathcal{K}^{d}$. Then

$$
r_{k}(K) \leq r_{k}^{\pi}(K) \leq k r_{k}(K) .
$$

Proof To prove the right inequality let $L$ be a $k$-plane, for which $\pi_{\llcorner }(K)$ contains a $k$-ball $B$ with radius $r_{k}^{\pi}(\mathrm{K})$. Let $S$ be a regular $k$-dimensional simplex with vertices on the relative boundary of B . S is the projection of a simplex $\mathrm{S}^{\prime}$ contained in K . As the ratio of the circumradius and the inradius of a regular $k$-simplex is $k$ (see [BF]), $\mathrm{S}^{\prime}$ contains a k -dimensional inball with radius $r_{k}^{\pi}(K) / k$. The other inequality is trivial.

The previous lemma and a result in [BH ] immediately give a convenient tool to estimate volume and surface area of convex bodies:

Lemma 2.7 Let $K \in \mathcal{K}^{d}$. Then there exist positive constants $C_{1}, C_{2}, C_{3}, C_{4}$ depending only on d such that

$$
\begin{aligned}
c_{1} r_{1}(K) \cdot \cdots \cdot r_{d}(K) & \leq V(K) \leq c_{2} r_{1}(K) \cdot \cdots \cdot r_{d}(K), \\
c_{3} r_{1}(K) \cdot \cdots \cdot r_{d-1}(K) & \leq S(K) \leq c_{4} r_{1}(K) \cdots \cdot r_{d-1}(K) .
\end{aligned}
$$

Finally we need a sufficiently interior point of a convex set $K$. This is provided by the center $\mathrm{c}(\mathrm{K})$ of a (relative) inball.

N ow we can state the facts needed in the proof of Theorem D:

Lemma 2.8 Let $K_{\lambda}$ bea family of convex bodies, such that $r_{d}\left(K_{\lambda}\right)$ and $r_{k}\left(K_{\lambda}\right) / r_{k+1}\left(K_{\lambda}\right)$ tend to infinity, but $r_{k+1}\left(K_{\lambda}\right) / r_{d}\left(K_{\lambda}\right)$ is bounded. Let $\omega_{\lambda}$ be a sequence of positive numbers with $\omega_{\lambda} \rightarrow 0$. Then for $L_{\lambda}=L^{k}\left(K_{\lambda}\right)$ and $M_{\lambda}=\left(1-\omega_{\lambda}\right) \pi_{L_{\lambda}}\left(K_{\lambda}\right)+\omega_{\lambda} \mathrm{C}\left(\pi_{L_{\lambda}}\left(K_{\lambda}\right)\right)$, we have
(a) for every $\varepsilon>0$ there is a $\lambda_{0}$ such that for all $\lambda>\lambda_{0}$ and $j=1, \ldots, k$

$$
\mathrm{r}_{\mathrm{j}}\left(\pi_{\mathrm{L}_{\lambda}}\left(\mathrm{K}_{\lambda}\right)\right) \geq(1-\varepsilon) \mathrm{r}_{\mathrm{j}}\left(\mathrm{~K}_{\lambda}\right)
$$

(b)

$$
\lim _{\lambda \rightarrow \infty} \frac{\mathcal{H}^{\mathrm{d}-1}\left(\left(\mathrm{M}_{\lambda}+\mathrm{L}_{\lambda}^{\perp}\right) \cap \partial \mathrm{K}_{\lambda}\right)}{S\left(\mathrm{~K}_{\lambda}\right)}=1 .
$$

Proof Let $\mathrm{B}_{\lambda}$ be a j-ball of radius $\mathrm{r}_{\mathrm{j}}\left(\mathrm{K}_{\lambda}\right)$ contained in $\mathrm{K}_{\lambda}, \mathrm{H}_{\lambda}$ be the affine plane spanned by $B_{\lambda}$ and $u_{1}^{\lambda}, \ldots, u_{j}^{\lambda}$ be an orthonormal basis of the linear plane parallel to $H^{\lambda}$. We may write $u_{i}^{\lambda}=v_{i}^{\lambda}+w_{i}^{\lambda}$ for $i=1, \ldots, j$ where $v_{i}^{\lambda}$ is in the linear plane parallel to $L_{\lambda}$ and $w_{i}^{\lambda}$ is in $L_{\lambda}^{\perp}$. Now $K_{\lambda} \subset L_{\lambda}+(k+2) r_{k+1}\left(K_{\lambda}\right) B^{d}$ and $r_{k+1}\left(K_{\lambda}\right) / r_{j}\left(K_{\lambda}\right) \rightarrow 0$ immediately show $\mathrm{w}_{\mathrm{i}}^{\lambda} \rightarrow 0$ for all i . (a) is a straightforward consequence.

Wemay assume that $\mathrm{C}\left(\pi_{\mathrm{L}_{\lambda}}\left(\mathrm{K}_{\lambda}\right)\right)$ is the origin. Then we have $\left(1-\omega_{\lambda}\right) \mathrm{K}_{\lambda} \subset\left(\mathrm{M}_{\lambda}+\mathrm{L}_{\lambda}{ }_{\lambda}\right) \cap$ $\mathrm{K}_{\lambda}$. From this we conclude

$$
\lim _{\lambda \rightarrow \infty} \frac{\mathrm{S}\left(\left(\mathrm{M}_{\lambda}+\mathrm{L}_{\lambda}^{\perp}\right) \cap \mathrm{K}_{\lambda}\right)}{\mathrm{S}\left(\mathrm{~K}_{\lambda}\right)}=1
$$

So it is sufficient to prove

$$
\lim _{\lambda \rightarrow \infty} \frac{\mathcal{H}^{d-1}\left(\bigcup_{x \in \partial M_{\lambda}}\left(x+L_{\lambda}^{\perp}\right) \cap K_{\lambda}\right)}{S\left(K_{\lambda}\right)}=0
$$

Among the sections ( $x+L_{\lambda}^{\perp}$ ) $\cap K_{\lambda}$ let $A$ be the one with largest ( $d-k$ )-measure. We have $\mathcal{H}^{d-k}(A) \leq c_{1} r_{k+1}^{d-k}$ for some constant $c_{1}$ by (6). The result follows by (a) from the estimates given in Lemma 2.7.

Finally we need that the volume of certain neighbourhoods of a piece of the boundary of a convex set cannot be too large.

Lemma 2.9 Let $K_{\lambda}, L_{\lambda}, \omega_{\lambda}$ and $M_{\lambda}$ be as in Lemma 2.8, and denote by $\sigma_{\lambda}$ the closure of $\partial K_{\lambda} \cap\left(\left(L_{\lambda} \backslash M_{\lambda}\right)+L_{\lambda}^{\perp}\right)$. Then for anyt $>0$,

$$
\lim _{\lambda \rightarrow \infty} \frac{\mathrm{V}\left(\mathrm{~N}\left(\sigma_{\lambda}, \mathrm{t}\right)\right)}{\mathrm{S}\left(\mathrm{~K}_{\lambda}\right)}=0
$$

Proof Approximating by polytopes, we may assume that $K_{\lambda}$ is actually a polytope. Set

$$
\tilde{M}_{\lambda}=\left(1-2 \omega_{\lambda}\right) \pi_{\mathrm{L}_{\lambda}}\left(\mathrm{K}_{\lambda}\right)+2 \omega_{\lambda} \mathrm{C}\left(\pi_{\mathrm{L}_{\lambda}}\left(\mathrm{K}_{\lambda}\right)\right)
$$

and

$$
\tilde{\sigma}_{\lambda}=\mathrm{cl}\left(\partial \mathrm{~K}_{\lambda} \cap\left(\left(\mathrm{L}_{\lambda} \backslash \tilde{M}_{\lambda}\right)+\mathrm{L}_{\lambda}^{\perp}\right)\right) .
$$

Denote by $\mathrm{N}_{\mathrm{k}}$ the set of points in $\mathrm{N}\left(\sigma_{\lambda}, \mathrm{t}\right)$ such that a closest point of $\partial \mathrm{K}_{\lambda}$ is in the relative interior of some $k$-face. O bserve that for any point in $N_{d-1}$ the closest point is in $\tilde{\sigma}_{\lambda}$ for $\lambda$ sufficiently large, and hence

$$
\mathrm{V}\left(\mathrm{~N}_{\mathrm{d}-1}\right) \leq 2 \mathrm{t} \cdot \mathcal{H}^{\mathrm{d}-1}\left(\tilde{\sigma}_{\lambda}\right) .
$$

We deduce by Lemma 2.8 (b) that

$$
\lim _{\lambda \rightarrow \infty} \frac{\mathrm{V}\left(\mathrm{~N}_{\mathrm{d}-1}\right)}{\mathrm{S}\left(\mathrm{~K}_{\lambda}\right)}=0
$$

Now we assume $k<d-1$. Then no point of $N_{k}$ is contained in the interior of $K_{\lambda}$, and hence the definition of the mixed volumes yields

$$
V\left(N_{k}\right) \leq\binom{ d}{k} V\left(K_{\lambda}, B^{d} ; d-k\right) \cdot t^{d-k}
$$

Since by the monotonicity of the mixed volumes, the inequalities

$$
V\left(K_{\lambda}, B^{d} ; d-k\right) \leq \frac{1}{r_{d}\left(K_{\lambda}\right)^{d-k-1}} \cdot V\left(K_{\lambda}, B^{d} ; 1\right)=\frac{1}{d \cdot r\left(K_{\lambda}\right)^{d-k-1}} \cdot S\left(K_{\lambda}\right)
$$

hold, we conclude the lemma.

## 3 Lipschitz Maps

We still keep $M$, $r$ and $R$ as in the previous section.
We need some very basic properties of a Lipschitz map. If f has Lipschitz constant $\gamma$, i.e., $\|f(x)-f(y)\| \leq \gamma \cdot\|x-y\|$ for all $x, y$, then

$$
\begin{equation*}
\mathcal{H}^{d-1}(\mathrm{f}(\sigma)) \leq \gamma^{\mathrm{d}-1} \cdot \mathcal{H}^{d-1}(\sigma) \tag{7}
\end{equation*}
$$

Lemma 3.1 Let $\Pi$ be a ( $\mathrm{d}-1$ )-dimensional convex, compact set and $\mathrm{t}>0$ be smaller than the relative inradius of $\Pi$. If $\mathrm{f}: \Pi \rightarrow \mathrm{E}^{\mathrm{d}}$ has Lipschitz constant $\gamma$ then

$$
V(N(f(\Pi), t))<2^{2(d-1)} \frac{V\left(B^{d}\right)}{\mathcal{H}^{d-1}\left(B^{d-1}\right)}(1+\gamma)^{d} \mathcal{H}^{d-1}(\Pi) \cdot t .
$$

Proof We may assume that the origin is the center of the largest ( $\mathrm{d}-1$ )-ball contained in $\Pi$ and $B^{d-1}$ is the unit ball in lin $\Pi$. Let $X \subset \Pi$ have maximal cardinality with the condition that any two elements of $X$ are at least distancet apart. Thus for $x, y \in X$ we have int $\left(\left(x+\frac{t}{2} B^{d-1}\right) \cap\left(y+\frac{t}{2} B^{d-1}\right)\right)=\varnothing,\left(X+t B^{d-1}\right) \subset 2 \Pi$ and $X+B^{d-1}$ covers $\Pi$. Thus $X$ has at most $\mathcal{H}^{d-1}(2 \Pi) / \mathcal{H}^{d-1}\left(\frac{1}{2} \mathrm{tB}^{d-1}\right)$ elements.

Wededuce that

$$
N(f(\Pi), t) \subset f(X)+(1+\gamma) t \mathbb{B}^{d},
$$

which in turn yields the lemma.
Now let $\mathrm{Q} \in \mathcal{K}^{d}$ such that $r B^{d} \subset \mathrm{Q} \subset \mathrm{RB}^{d}$. Then thereexists some positive $\mathrm{c}_{1}$ depending on $r$ and $R$ such that if $y, z \in \partial Q$ then

$$
\frac{1}{c_{1}} \cdot \delta(y, z)<\angle(y, z)<c_{1} \cdot \delta(y, z) .
$$

Similarly, there exists some positive $\mathrm{c}_{2}$ depending on r and R such that if H is some hyperplanesupporting M at $\mathrm{x} \in \partial \mathrm{M}$ and $\mathrm{y}, \mathrm{z} \in \mathrm{N}\left(\mathrm{x}, \frac{1}{2} \mathrm{r}\right) \cap \mathrm{H}$ then

$$
\frac{1}{c_{2}} \cdot \delta(y, z)<\angle(y, z)<c_{2} \cdot \delta(y, z) .
$$

We conclude
Lemma 3.2 There exists a c depending on $r, R$ and $d$ and an $\omega>0$ depending on $M$ with the following property:

Let H bea hyperplanesupporting at $\mathrm{x} \in \partial \mathrm{M}$ and Q bea convex body with $\Delta^{\mathrm{H}}(\mathrm{Q}, \mathrm{M})<\omega$. Then for $\mathrm{y}, \mathrm{z} \in \mathrm{N}\left(\mathrm{x}, \frac{1}{2} \mathrm{r}\right) \cap \mathrm{H}$,

$$
\frac{1}{\mathrm{c}} \cdot \delta\left(\pi_{\partial Q}(\mathrm{y}), \pi_{\partial Q}(\mathrm{z})\right)<\delta(\mathrm{y}, \mathrm{z})<\mathrm{c} \cdot \delta\left(\pi_{\partial Q}(\mathrm{y}), \pi_{\partial Q}(\mathrm{z})\right)
$$

We say that $T$ is a tangent polytope of $M$ if every facet $F$ of $T$ touches $M$ and $F \subset$ $N\left(F \cap M, \frac{1}{2} r\right)$. We deduce by Lemma 3.2 that for $\Delta^{H}(Q, M)<\omega$ (where $\omega$ comes from Lemma 3.2) $\pi_{\partial Q}$ is Lipschitz on $\partial T$ and $\pi_{\partial \tau}$ is Lipschitz on $\partial Q$.

For positive k and a ( $\mathrm{d}-1$ )-polytope F we construct k -patches on F in the following way: We choose a tiling of aff $F$ by $(d-1)$-cubes with edge length $1 / k$, and call a ( $d-$ 1)-dimensional intersection of some tile and F a k-patch. We obtain a dissection of the boundary of a polytopeT by taking all the $k$ - patches of its facets. In general for $P \in \mathscr{K}^{d}$ with $0 \in \operatorname{int} P$ and a polytope $T$ with $0 \in \operatorname{int} T$ the $k$-patches on $\partial P$ are the radial projections of thek-patches on $\partial T$.

Lemma 3.3 Let $\eta>0$. There exists some compact $\varrho_{\eta} \subset \partial \mathrm{M}$ with $\mathcal{H}^{\mathrm{d}-1}\left(\varrho_{\eta}\right)=0$ and a C depending only on r , R such that if $\delta(\mathrm{x}, \mathrm{y})<\theta$ and $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}\right) \geq \eta$ hold for outer normals $\mathrm{n}_{\mathrm{x}}$ at $x \in \partial \mathrm{M}$ and $\mathrm{n}_{\mathrm{y}}$ at $\mathrm{y} \in \partial \mathrm{M}$ then $\mathrm{x}, \mathrm{y} \in \mathrm{N}\left(\varrho_{\eta}, \mathrm{c} \cdot \theta\right)$.

Proof Choose k so that any k patch on $2 \mathrm{RS}^{\mathrm{d}-1}$ has diameter at most $\mathrm{R} \sin \frac{1}{2} \eta$ and denote by $\varrho_{0}$ the union of the (relative) boundaries of these patches on 2 RS $^{d-1}$. Writing $\mathrm{p}_{\mathrm{M}}(\mathrm{x})$ for the closest point of $x$ to $M$, we have that $\varrho=p_{M}\left(\varrho_{0}\right)$ has zero $\mathcal{H}^{d-1}$ measure since $p_{M}$ is Lipschitz (see[S]) and $\mathcal{H}^{d-1}\left(\varrho_{0}\right)=0$.

Assume that suitable x and y are given. There exists a continuous curve $\xi$ on $\partial \mathrm{M}$ connecting $x$ and $y$ with length less then $c \cdot \theta$ where $c$ depends on $r$, R. We claim that $\xi_{0}=\mathrm{p}_{\mathrm{M}}^{-1}(\xi) \cap 2 \mathrm{RS}^{\mathrm{d}-1}$ is connected: Else there exist disjoint compact sets $\xi_{1}, \xi_{2}$ with $\xi_{0}=\xi_{1} \cup \xi_{2}$. Now there exists an $\mathrm{x} \in \mathrm{p}_{\mathrm{M}}\left(\xi_{1}\right) \cap \mathrm{p}_{\mathrm{M}}\left(\xi_{2}\right)$,as $\mathrm{p}_{\mathrm{M}}\left(\xi_{1}\right)$ and $\mathrm{p}_{\mathrm{M}}\left(\xi_{2}\right)$ are compact and $\xi$ is connected. Thus $\mathrm{p}_{\mathrm{M}}^{-1}(\mathrm{x}) \cap 2 \mathrm{RS}^{\mathrm{d}-1}$ is disconnected. But this is a contradiction as clearly $\mathrm{p}_{\mathrm{M}}^{-1}(\mathrm{z}) \cap 2 \mathrm{RS}^{\mathrm{d}-1}$ is connected for all $\mathrm{z} \in \xi$.

Let $x_{0}\left(y_{0}\right)$ be the inverse image of $x(y)$ generated by $n_{x}\left(n_{y}\right)$, and let $y_{0}^{\prime}$ be the intersection of $2 \mathrm{RS}^{\mathrm{d}-1}$ and the ray starting from x parallel to $\mathrm{n}_{\mathrm{y}}$. Thus $\delta\left(\mathrm{x}_{0}, \mathrm{y}_{0}^{\prime}\right)>2 \mathrm{R} \sin \frac{1}{2} \eta$, and for small $\theta$, we have $\delta\left(x_{0}, y_{0}\right)>R \sin \frac{1}{2} \eta$. Thus $x_{0}, y_{0}$ are contained in different patches of 2R $S^{d-1}$. We conclude, that $\xi_{0} \cap \varrho_{0} \neq \varnothing$ as otherwise there would be a dissection of $\xi_{0}$ in two non-empty open sets. Consequently $\xi \cap \varrho$ is non-empty too.

In view of the previous lemma it is of interest to look at the neighbourhood of compact sets with zero measure. Here we have

Lemma 3.4 Let $T$ bea polytope, $\varrho \subset \partial T$ compact and $\mathcal{H}^{\mathrm{d}-1}(\varrho)=0$. For every $\mathrm{k} \in \mathrm{N}$ let K denote the set of $k$-patches $\Pi$ on $\partial T$ such that for every $\Pi \in K$ we have $\Pi \cap N(\varrho, 1 / k) \neq \varnothing$. Then for every $\varepsilon>0$ there exists $\mathrm{k} \in \mathrm{N}$ such that $\sum_{\Pi \in \mathrm{K}} \mathcal{H}^{\mathrm{d}-1}(\Pi)<\varepsilon$.

Proof By considering the facets separately, it is sufficient to prove for compact $\varrho \subset \mathrm{E}^{\mathrm{d}-1}$ with $\mathcal{H}^{d-1}(\varrho)=0$ that there is a $\tau>0$ such that $\mathcal{F}^{d-1}(N(\varrho, \tau))<\varepsilon$.

As(d - 1)-dimensional Hausdorff-measure and Lesbesgue-measure coincide we have by definition of the measure an open set G containing $\varrho$ with $\mathcal{H}^{\mathrm{d}-1}(\mathrm{G})<\varepsilon$. For each $\mathrm{x} \in \varrho$, let $\tau(\mathrm{x})>0$ be the maximal radius such that $\mathrm{N}(\mathrm{x}, \tau(\mathrm{x})) \subset \mathrm{G}$. Clearly $\tau(\mathrm{x})$ is continuous, and hence $\tau$ can be chosen as the positive minimum of $\tau(\mathrm{x})$.

## 4 Some Properties of Bounded Lattice Vectors

We establish some simple properties for lattice vectors. The first lemma shows that a family of lattice vectors with bounded length is not too sparse, but it is also not too "dense" according to the second lemma. We close with an observation concerning the approximation of arbitrary planes by lattice planes in a way that the approximating plane contains short lattice vectors.

Lemma 4.1 For every $\chi>0$ there exists an $\mathrm{n}_{0}$ with the following property: Let $0 \leq \psi \leq 1$. Then thereis an $(\mathrm{n}, \mathrm{m}) \in \mathrm{Z}^{2}$ with $\mathrm{n} \leq \mathrm{n}_{0}$ such that $\angle((1, \psi),(\mathrm{n}, \mathrm{m})) \leq \chi$ and $|\mathrm{n} \cdot \psi-\mathrm{m}|<$ $1 / n$.

Proof We observe that for given $\chi$ there exists a $\delta>0$ such that $\angle((1, \psi),(1, \eta))<\chi$ for all $\eta$ with $|\psi-\eta|<\delta$. Let $\mathrm{n}_{0}=\lceil 1 / \delta\rceil$. By a fundamental theorem from Diophantine Approximation there exists an $\mathrm{n} \leq \mathrm{n}_{0}$ and $\mathrm{m} \in \mathrm{Z}$ such that $\left|\psi-\frac{m}{n}\right|<\frac{1}{\mathrm{n} \cdot \mathrm{n}_{0}}$ (see [C], [GL]).

Apparently ( $\mathrm{n}, \mathrm{m}$ ) has the required properties.

Let $\mathrm{e}_{1}, \ldots, \mathrm{e}_{\mathrm{d}}$ denotethe canonical basis of $\mathrm{Z}^{\mathrm{d}}$, and $\operatorname{set} \mathrm{P}_{\mathrm{ij}}=\operatorname{lin}\left\{\mathrm{e}, \mathrm{e}_{\mathrm{j}}\right\}$.
Lemma 4.2 For (large) $\varphi$, let $\mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{m}} \in \mathrm{S}^{\mathrm{d}-1}$ bethenormals of the sub ( $\mathrm{d}-1$ )- lattices of $Z^{\mathrm{d}}$ such that $\left\langle\mathrm{u}_{\mathrm{i}}, \mathrm{e}_{1}\right\rangle>1 /(2 \sqrt{\mathrm{~d}})$ and each $\mathrm{P}_{1 \mathrm{i}}, \mathrm{i}=2, \ldots, \mathrm{~d}$, contains a non-zero lattice vector of length at most $\varphi$ of the sublattice. Then for any (small) positive $\alpha$ there exists a positive $\beta$ with the following property:

For any $v \in S^{d-1}$, with $\angle\left(v, u_{j}\right)>\alpha$ for $j=1, \ldots, m$, and $\left\langle v, e_{1}\right\rangle>1 /(2 \sqrt{d})$, there exists an $\mathrm{i} \geq 2$ such that if $\mathrm{v}_{\mathrm{i}} \in \mathrm{S}^{\mathrm{d}-1} \cap \mathrm{P}_{\mathrm{i}}$ is perpendicular to v and $\angle\left(\mathrm{w}, \mathrm{v}_{\mathrm{i}}\right)<\beta$ for a primitive $w \in Z^{\mathrm{d}} \cap \mathrm{P}_{1 i}$ then the length of w is greater than $\varphi$.

Proof We denote the set of unit vectors v satisfying $\left\langle\mathrm{v}, \mathrm{e}_{1}\right\rangle \geq 1 /(2 \sqrt{\mathrm{~d}})$ by $\Omega$. For any $\mathrm{i}=2, \ldots$, d the map $v \mapsto \mathrm{v}_{\mathrm{i}}^{\prime}$ on $\Omega$ is continuous where the unit vector $\mathrm{v}_{\mathrm{i}}^{\prime} \in \mathrm{S}^{d-1} \cap \mathrm{P}_{1 \mathrm{i}}$ is parallel to the orthogonal projection of $v$ onto $\mathrm{P}_{1 \mathrm{i}}$. We may choose $\mathrm{v}_{\mathrm{i}} \in \mathrm{S}^{\mathrm{d}-1} \cap \mathrm{P}_{1 \mathrm{i}}$ orthogonal to $v_{i}^{\prime}$ (and hence also to $v$ ) so that the map $v \mapsto v_{i}$ is still continuous. We set

$$
f(v)=\max _{i=2, \ldots, d} \min \left\{\angle\left(v_{i}, w\right) \mid w \in P_{1 i} \cap Z^{d} \text { and }\|w\| \leq \varphi\right\} .
$$

Clearly we have $\mathrm{f}(\mathrm{v}) \neq 0$ for $\mathrm{v} \notin\left\{\mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{m}}\right\}$. Now for $\alpha>0$, let

$$
\Omega_{\alpha}=\left\{v \in \Omega \mid \angle\left(v, u_{j}\right) \geq \alpha \forall j=1, \ldots, m\right\} .
$$

Since $\Omega_{\alpha}$ is compact and $\mathrm{f}(\mathrm{v})$ is continuous, $\beta$ can be chosen as the minimum of f on $\Omega_{\alpha}$ (assuming that $\Omega_{\alpha} \neq \varnothing$ ).

A M inkowski reduced basis $w_{1}, \ldots, w_{d}$ of a lattice $\Lambda$ is defined as follows: $w_{1}$ is a shortest vector, and $w_{k}$ is a shortest vector of $\Lambda$ not contained in $\operatorname{lin}\left\{w_{1}, \ldots, w_{k-1}\right\}$. Then there exists a positive constant c depending only on d (see [GL, p. 150]) such that c $\left\|W_{d}\right\| B^{d}$ contains no d independent lattice points.

Lemma 4.3 For every linear $k$-plane $\tilde{\sim} \subset R^{d}$ and every $\varepsilon>0$ there exist a lattice $k$-plane $L$ of $Z^{d}$ such that for a $M$ inkowski reduced basis $w_{1}, \ldots, w_{k}$ of $L \cap Z^{d}$,
(a) the distance of any point of

$$
\mathrm{T}=\left\{\sum_{\mathrm{i}=1}^{\mathrm{k}} \alpha_{\mathrm{i}} \mathrm{w}_{\mathrm{i}} \mid 0 \leq \alpha_{\mathrm{i}}<1\right\}
$$

from $\tilde{L}$ is at most $\varepsilon$, and
(b) for any unit normal $u$ to $\tilde{L}$ there exists an unit normal $v$ to L such that $\angle(\mathrm{u}, \mathrm{v})<\varepsilon$.

Proof We choose an orthonormal basis $\left(u_{11}, \ldots, u_{1 d}\right), \ldots,\left(u_{k 1}, \ldots, u_{k d}\right)$ of $\tilde{L}$. Now we use simultaneous Diophantine approximation for the kd numbers $\mathrm{u}_{\mathrm{ij}}$. By a well known theorem (see [GL, p. 44] or [C]) there are infinitely many $q \in N$ such that there exist $\mathrm{p}_{\mathrm{ij}} \in \mathrm{Z}, 1 \leq \mathrm{i} \leq \mathrm{k}, 1 \leq \mathrm{j} \leq \mathrm{d}$ with

$$
\left|u_{i j}-\frac{p_{i j}}{q}\right| \leq \frac{1}{q^{1+\frac{1}{k}}} .
$$

From this it follows that there are constants $c_{1}$ and $c_{2}$ depending only on $d$ such that for infinitely many $\mathrm{q} \in \mathrm{N}$ there are $\mathrm{v}_{1}, \ldots, \mathrm{v}_{\mathrm{k}} \in \mathrm{Z}^{\mathrm{d}}$ such that $\left\|\mathrm{v}_{\mathrm{i}}\right\| \leq \mathrm{c}_{1} \cdot \mathrm{q}$ and

$$
\angle\left(v_{i}, u_{i}\right)<\frac{c_{2}}{q^{1+\frac{1}{q_{d}}}} .
$$

Let $L$ be the plane spanned by $v_{1}, \ldots, v_{k}$ which satisfies (b) for largeq, even replacing $\varepsilon$ with $c_{3} / q^{1+\frac{1}{k 0}}$, where $c_{3}$ is a constant. If $w_{1}, \ldots, w_{k}$ is a Minkowski reduced bases of $L \cap Z^{d}$ then diam $T<c_{4} q$, where $c_{4}$ is a constant, which in turn yields (a) for largeq.

## 5 The Proof of Theorem B

We observethat all our statements are invariant under simultaneouslinear transformations of the lattice and the convex bodies. Thus we may assume that $\Lambda=Z^{\mathrm{d}}$. In this section $z$ always is a lattice point and $W(z)=z+\left[-\frac{1}{2}, \frac{1}{2}\right)^{d}$.

For $\mathrm{Q} \in \mathscr{K}^{d}$ we have the trivial identity

$$
\begin{equation*}
|G(Q)-V(Q)|=\left|\sum_{\substack{z \in Q \\ W(z) \cap O Q Q \neq \varnothing}} V(W(z) \backslash Q)-\sum_{\substack{z \notin Q \\ W(z) \cap \partial Q \neq \varnothing}} V(W(z) \cap Q)\right| . \tag{8}
\end{equation*}
$$

The basic idea of Theorem B is that we can rather easily estimate $G-V$ for the union of certain towers. To this end we introduce the notion of an $i$-box on the boundary of $Q$ for $i=1, \ldots$, d. We say that for $z=\left(z_{1}, \ldots, z_{d}\right)$ that $U$ is an $i$-box at $z$, if

$$
U=\left\{x=\left(x_{1}, \ldots, x_{d}\right) \mid x \in \partial Q,-\frac{1}{2} \leq z_{p}-x_{p}<\frac{1}{2}, p \neq i,\left\langle n_{x}, e\right\rangle>0\right\} .
$$

Analogously therearei-boxes for -e . We say that a box U is simple, if $\mathrm{Z} \cap \mathrm{U}=\mathrm{Z} \cap \partial \mathrm{Q}$ for the i-tower $Z$ with $Z \cap U \neq \varnothing$. For the union of certain simpleboxes we can easily estimate G-V.

Lemma 5.1 Let $\left\{U_{0}, \ldots, U_{q-1}\right\}$ be a set of simple 1 -boxes at $\mathrm{z}_{\mathrm{i}}, \mathrm{i}=0, \ldots, \mathrm{q}-1$ such that

$$
z_{i}+\left(\frac{i}{q}+\alpha_{i}\right) e_{1} \in \partial Q
$$

with $-1 / \mathrm{q}<\alpha_{\mathrm{i}}<1 / \mathrm{q}$ for $\mathrm{i}=0, \ldots, \mathrm{q}-1$. Finally let dev $\mathrm{Z}_{\mathrm{i}}<\epsilon$ for every one tower $\mathrm{Z}_{\mathrm{i}}$ at $\mathrm{z}_{\mathrm{i}}+\left(\frac{i}{\mathrm{q}}+\alpha_{\mathrm{i}}\right) \mathrm{e}_{\mathrm{i}}$. Then

$$
\left|\sum_{i=0}^{q-1}\left(\sum_{z \in Z_{i}, z \in Q} V(W(z) \backslash Q)-\sum_{z \in Z_{i}, z \notin Q} V(W(z) \cap Q)\right) \pm \frac{1}{2}+\sum_{i=0}^{q-1} \alpha_{i}\right| \leq q \varepsilon .
$$

Here we have " + ", if $\alpha_{0}<0$ and " - " otherwise.

Proof By the definition of the deviation in Section 2 and writing $\{a\}$ for thefractional part of a we have

$$
\left|\sum_{\substack{z \in Z_{i} \\ z \in Q}} V(W(z) \backslash Q)-\sum_{\substack{z \in Z_{i} \\ z \notin Q}} V(W(z) \cap Q)-\frac{1}{2}+\frac{i}{q}+\alpha_{i}\right| \leq \varepsilon
$$

for $\frac{i}{q}+\alpha_{i} \in[0,1 / 2]$ and

$$
\left|\sum_{\substack{z \in Z_{i} \\ z \in Q}} V(W(z) \backslash Q)-\sum_{\substack{z \in Z_{i} \\ z \notin Q}} V(W(z) \cap Q)+\frac{1}{2}+\frac{i}{q}+\alpha_{i}\right| \leq \varepsilon
$$

for $\frac{i}{q}+\alpha_{i} \in(1 / 2,1)$. The lemma is an immediate consequence.

We shall see that Theorem B is a consequence of the fact, that for large $\lambda$ most of $\partial \lambda Q$ can be covered appropriate unions of sufficiently flat simpleboxes. As a first application we give a proof of Theorem A:

Proof of Theorem A Let $F$ be a facet of the lattice-facet polytope $Q$ with primitive exterior normal $u \in Z^{d}$. Set $L=Z^{d} \cap \operatorname{lin}(F-F)$ and $q=\operatorname{det} L$. Wemay assumethat $u=\left(u_{1}, \ldots, u_{d}\right)$ with $u_{1}>0$.

Let $P$ be a fundamental cell of $L$. There are exactly $q$ points $z_{0}, \ldots, z_{q-1} \in Z^{d}$ such that $w_{i}=z_{i}+\frac{i}{q} e_{1} \in P$. We have aff $F=\operatorname{lin}(F-F)+t e_{1}$ for somet $\in R$. There is a renumbering $\tilde{\mathrm{w}}_{0}, \ldots, \tilde{\mathrm{w}}_{\mathrm{q}-1}$ of $\mathrm{w}_{1}, \ldots, \mathrm{w}_{\mathrm{q}-1}$ such that

$$
\tilde{w}_{i}+\lambda t e_{1}=\tilde{z}_{i}+\left(\frac{i}{q}+\alpha\right) e_{1}
$$

for suitable $\tilde{z}_{i} \in Z^{d}$ and

$$
\begin{equation*}
-1 /(2 q) \leq \alpha<1 /(2 q) \tag{9}
\end{equation*}
$$

Now let $\nu>0$ befixed and

$$
L_{0}(\lambda)=\left\{I \in L \mid w_{i}+\lambda t e_{1}+I \in \lambda F_{-\nu / 2}, i=0, \ldots, q-1\right\} .
$$

Then every $\mid \in L_{0}(\lambda)$ defines a set of simple 1-boxes $U_{0,1}, \ldots, U_{q-1, I}$ at $\tilde{z}_{0}+I, \ldots, \tilde{z}_{q-1}+\mid$ such that

$$
\lambda \mathrm{F}_{-\nu} \subset \bigcup_{\mathrm{I} \in \mathrm{~L}_{0}}\left(\mathrm{U}_{1, \mathrm{I}} \cup \cdots \cup \mathrm{U}_{\mathrm{q}-1, \mathrm{I}}\right)
$$

Thus Lemma 5.1 yields with $\epsilon=0$

$$
\begin{aligned}
& \left|\sum_{1 \in L_{0}(\lambda)} \sum_{i=0}^{q-1}\left(\sum_{\substack{z \in \lambda Q, W(z) \cap \cup \cup \in \varnothing}} V(W(z) \lambda Q)-\sum_{\substack{z \notin \lambda Q, W(z) \cap U \\
\text { in }}} V(W(z) \cap \lambda Q)\right)\right| \\
& =\sum_{1 \in \mathrm{~L}_{0}(\lambda)}\left(\frac{1}{2}-\mathrm{q}|\alpha|\right) \\
& =\left(\frac{1}{2}-\mathrm{q}|\alpha|\right) \frac{\mathcal{H}^{\mathrm{d}-1} \lambda \mathrm{~F}}{\operatorname{det} \mathrm{~L}}+\mathrm{O}\left(\nu \cdot \lambda^{\mathrm{d}-2}\right) \text {. }
\end{aligned}
$$

Since at most $\mathrm{O}\left(\nu \cdot \lambda^{\mathrm{d}-2}\right)$ cubes $\mathrm{W}(\mathrm{z})$ and at most $\mathrm{O}\left(\nu \cdot \lambda^{\mathrm{d}-2}\right)$ of the surface area were not taken into account, the theorem follows.

The proof of Theorem B is quite analoguous to that of Theorem A. We approximate the boundary of $M$ by $k$-patches (cf. the definition in Section 3 ). We distinguish between flat patches which can be considered as a substitute for facets and bended patches. Among the flat patches we distinguish further between facets parallel to lattice hyperplanes, "good" patches, for which the normals are not to close to the normals of lattice hyperplanes with small determinant and some remaining "bad" patches. For the lattice facets and the good patches we can apply Lemma 5.1 and for the bended and bad patches we show that there are not too many of them. We prove Theorem B in the apparently equivalent form:

Theorem 5.2 Let $M \in \mathcal{K}^{d}$. For any $\varepsilon>0$ there exist positive $\lambda_{0}$ and $\omega$ such that for all $\mathrm{Q} \in \mathcal{K}^{\mathrm{d}}$ with $\Delta^{\mathrm{H}}(\mathrm{M}, \mathrm{Q})<\omega$ and all $\lambda>\lambda_{0}$

$$
|G(\lambda Q)-V(\lambda Q)| \leq \frac{1}{2} S_{Z^{d}}(M) \cdot \lambda^{d-1}+\varepsilon \cdot \lambda^{d-1} .
$$

As the proof of Theorem 5.2 is somewhat longish, we shall split it into several lemmas. First we observe that we may assume that $S(M)=1$, and as the surface area is continuous, also that $S(Q)=1$. Further thereare positiver, $R$ such that for somet $\in E^{d} r B^{d}+t \subset$ int $M$ and $M \subset \operatorname{intRB} B^{d}+t$. Now let some $\varepsilon>0$ be given.

We start with the construction of a suitable tangent polytope and associated patches (for the definitions see Section 3). First we identify the lattice hyperplanes such that the facets in the hyperplanes could make significant contributions to $\mathrm{G}-\mathrm{V}$. Let H be a lattice hyperplane, such that e $\notin \mathrm{H}$. Now let us assume that for $\mathrm{j}=1, \ldots, \mathrm{~d}, \mathrm{j} \neq \mathrm{i}$, there is a lattice vector of length at most $\phi$ in $\mathrm{H} \cap \mathrm{P}_{\mathrm{ij}}$ (the definition of $\mathrm{P}_{\mathrm{ij}}$ is in Section 4). Then the lattice $\mathrm{Z}^{\mathrm{d}} \cap \mathrm{H}$ has determinant less than $\phi^{\mathrm{d}-1}$. Thus for $\phi=5 / \varepsilon$ there exists an $\mathrm{m}_{0} \in \mathrm{~N}$ such that $u_{1}, \ldots, u_{m_{0}} \in S^{d-1}$ are the normals of the sub ( $\mathrm{d}-1$ )-Iattices such that for some i we have $\left\langle\mathrm{e}, \mathrm{u}_{\mathrm{k}}\right\rangle \neq 0$ and each $\mathrm{P}_{\mathrm{i}}, \mathrm{j} \neq \mathrm{i}$, contains a non-zero lattice vector of length at most $\phi$ of the sublattice. We enumerate the $u_{k}$ such that for $k=1, \ldots, m_{1}$ we have $\mathcal{F}^{d-1}\left(F_{M}\left(u_{k}\right)\right)>0$ and for $k=m_{1}+1, \ldots$, m whave $\mathcal{H}^{d-1}\left(F_{M}\left(u_{k}\right)\right)=0$.

Now let $T$ be a fixed tangent polytope of $M$ that has $u_{1}, \ldots, u_{m_{0}}$ in its set of normal vectors. We note $\mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{k}}\right) \subset \partial \mathrm{T}$ for $\mathrm{k}=1, \ldots, \mathrm{~m}_{0}$. By Lemma 3.2, there exist c , $\omega_{0}$ depending only on $M$ such that for $\Delta^{H}(Q, M)<\omega_{0}$ the maps $\pi_{\partial Q}: \partial T \rightarrow \partial Q$ and $\pi_{\partial T}: \partial Q \rightarrow \partial T$
have Lipschitz constant c. By possibly taking c larger we may further assume by (7) that for measurable $\sigma \subset \partial \mathrm{T}$ the formula

$$
\begin{equation*}
\mathcal{H}^{\mathrm{d}-1}\left(\pi_{\partial Q}(\sigma)\right) \leq \mathrm{C} \cdot \mathcal{H}^{\mathrm{d}-1}(\sigma) \tag{10}
\end{equation*}
$$

holds. From now on we assume without further mentioning that $\Delta^{H}(Q, M)<\omega_{0}$.
In the next step we construct a $k$ such that the $k$-patches have the right properties. We write $\varrho_{\mathrm{i}}$ for the boundary of $\pi_{\partial \mathrm{T}}\left(\mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right)\right)$ with respect to $\partial \mathrm{T}$ and $\sigma_{\mathrm{i}}(\mathrm{k})$ for the union of k patches on $\partial \mathrm{T}$ which intersect $\partial \mathrm{T} \cap \mathrm{N}\left(\varrho_{i}, 1 / \mathrm{k}\right)$. By Lemma 3.1 there exists a $\mathrm{k}_{1}$ and a $\lambda_{0}$ such that for all $\lambda>\lambda_{0}$

$$
\begin{equation*}
\sum_{i=1}^{m} V\left(N\left(\lambda \cdot \pi_{\partial Q}\left(\sigma_{i}\left(k_{1}\right)\right), \sqrt{d}\right)\right)<\frac{\varepsilon}{8} \lambda^{d-1} . \tag{11}
\end{equation*}
$$

Further we observe that by Lemma 2.2 there exist positive $\alpha$ and $\omega_{1}<\omega_{0}$ such that for all $\omega<\omega_{1}$

$$
\begin{equation*}
\psi_{Q}\left(N_{S^{d}-1}\left(u_{i}, \alpha\right)\right) \subset \pi_{\partial Q}\left(\sigma_{\mathrm{i}}\left(\mathrm{k}_{1}\right) \cup \mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right)\right) . \tag{12}
\end{equation*}
$$

Consequently we assume from now that $\Delta^{\mathrm{H}}(\mathrm{Q}, \mathrm{M})<\omega_{1}$ and k is a suitable multiple of $\mathrm{k}_{1}$.

In the next step we assure that most patches become sufficiently flat. Let $\beta_{1}$ be the angle given by Lemma 4.2 for the $\alpha$ above, $n_{0}$ the smallest integer which satisfies $n_{0} \geq 5 / \varepsilon$ and $1 / n_{0}^{2} \leq \tan \beta_{1}$, and $\beta_{2}=\angle\left((1,1),\left(1,1-1 / n_{0}^{2}\right)\right)$. Now let $\eta_{1}=\eta / 2$ for the angle $\eta$ given by Lemma 2.5 for $\gamma=\arccos \frac{1}{\sqrt{2 d}}$ and $\xi=\min \left\{\beta_{1}, \beta_{2}\right\}, \eta_{2}$ behalf of the angle $\gamma$ provided by Lemma 2.4 for $\beta=1 /(2 \sqrt{\mathrm{~d}}), \eta=\min \left\{\eta_{1}, \eta_{2}\right\}$ and for $\varepsilon / 10$ in place of $\varepsilon$.

For this $\eta$ we construct the set $\varrho_{\eta}$ from Lemma 3.3. We write $\varrho(\mathrm{k})$ for the union of k patches which intersect $N\left(\pi_{\partial \tau}\left(\varrho_{\eta}\right), 1 / k\right)$. By Lemma 3.4 and Lemma 3.1 we can find a multiple $k_{2}$ of $\mathrm{k}_{1}$ such that

$$
\begin{equation*}
\vee\left(N\left(\lambda \cdot \pi_{\partial Q}\left(\varrho\left(k_{2}\right)\right), \sqrt{d}\right)\right)<\frac{\varepsilon}{8} \lambda^{d-1} . \tag{13}
\end{equation*}
$$

Now we can further subdivide the patches, such that most of them become very flat on $M$ : By Lemma 3.3 there is a multiple $k_{3}$ of $k_{2}$ such that all $k_{3}$-patches $\Pi$ on $M$ satisfying $\Pi \not \subset \pi_{\partial M}\left(\varrho\left(k_{2}\right)\right)$ have the property that for $\mathrm{x}, \mathrm{y} \in \Pi$ thenormals $\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}$ satisfy $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}\right)<$ $\eta$. We subsume our discussion in the following

Lemma 5.3 There is a $k \in N$ such that there are $k$-patches on $M$ which can be partitioned into three classes:
(a) Patches, which are contained in the facets $\mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right), \mathrm{i}=1, \ldots, \mathrm{~m}_{1}$ of M .
(b) $\mathrm{m}_{2}$ patches $\Pi_{\mathrm{q}}$, such that for the numbers $\alpha, \eta$ given above all $\mathrm{x}, \mathrm{y} \in \Pi_{\mathrm{q}}$ satisfy $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}\right)<\eta$ and $\angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{u}_{\mathrm{i}}\right)>\alpha$ for $\mathrm{i}=1, \ldots, \mathrm{~m}_{0}$.
(c) Patches, which are not enumerated in (a) and (b). Their union $\varrho$ satisfies $V\left(N\left(\lambda \pi_{Q}(\varrho), \sqrt{d}\right)\right)<\frac{\varepsilon}{4} \lambda^{d-1}$.

We do the summation in (8) separately for the patches listed in (a), (b) and (c) above. Let us start with the facets $F_{M}\left(u_{r}\right), r=1, \ldots, m_{1}$. For a fixed facet $F=F_{M}\left(u_{r}\right)$ and $u=u_{r}$, define $L, q, z_{0}, \ldots, z_{q-1}$ and $\nu$ as in the the proof of Theorem A. By Lemma 2.3 we may further assume that if $Z$ is a 1-tower at $w \in \pi_{\partial \lambda Q}\left((\lambda F)_{-\nu / 2}\right)$ then $\operatorname{dev} Z<\frac{1}{16} \varepsilon$. Then we can proceed exactly as in the proof of Theorem A. We only have to observe, that the parameterst, $\alpha$ now depend on I and $i$, we have to replace (9) by

$$
-1 /(2 q)-\epsilon / 16 \leq \alpha<1 /(2 q)+\epsilon / 16
$$

and have to apply Lemma 5.1 with $\epsilon / 16$ instead of 0 . Altogether we obtain (a) below and Lemma 3.1 yields (b):

Lemma 5.4 Let $F$ be a facet of $M$ with normal $u_{r}, r \in\left\{1, \ldots, m_{1}\right\}$. Then there exist $\nu, \omega, \lambda_{0}>0$ such that for $\Delta^{H}(\mathrm{Q}, \mathrm{M}) \leq \omega$ and $\lambda>\lambda_{0}$
(a)

$$
\begin{aligned}
& \left|\sum_{\substack{z \in \lambda Q, W(z) \cap \pi_{\partial \lambda \curlywedge}\left((\lambda F)_{-\nu}\right) \neq \varnothing}} V(W(z) \backslash \lambda Q)-\sum_{\substack{z \notin \lambda Q, W(z) \cap \pi_{\partial \lambda \cap}\left((\lambda F)_{-\nu}\right) \neq \varnothing}} V(W(z) \cap \lambda Q)\right| \\
& \leq \frac{1}{2} \cdot \frac{\mathcal{H}^{d-1}(\lambda F)}{\operatorname{det}\left(u_{i}^{\perp} \cap Z^{d}\right)}+\frac{\varepsilon}{4} \mathcal{H}^{d-1}(\lambda F),
\end{aligned}
$$

(b) $\vee\left(N\left(\lambda \pi_{\partial Q}\left(F \backslash F_{-\nu}\right), \sqrt{d}\right)\right)<\frac{\varepsilon}{8 m_{1}} \lambda^{d-1}$.

Next, consider the patches in Lemma 5.3 (b). For $z=\left(z_{1}, \ldots, z_{d}\right) \in Z^{d}$, we call an $\mathrm{U} \subset \lambda \partial \mathrm{Q}$ an $(\mathrm{i}, \mathrm{j})$-strip of length q at z , if

$$
\begin{aligned}
U=\left\{x=\left(x_{1}, \ldots, x_{d}\right) \mid\right. & x \in \partial Q,\left|z_{p}-x_{p}\right| \leq \frac{1}{2} \\
& \left.p \neq i, j,\left\langle n_{x}, e_{1}\right\rangle>0,-\frac{1}{2} \leq x_{j}-z_{j} \leq q-\frac{1}{2}\right\} .
\end{aligned}
$$

Analogously there are $(i, j)$-strips for $-e$. We say that $U$ is simple if it is the union of $q$ simplei-boxes.

Lemma 5.5 Let $\Pi$ bea patch from Lemma 5.3 (b).
(a) There exist $\nu>0$ and $\lambda_{0}>0$ such that for all $\lambda>\lambda_{0}$

$$
\mathrm{V}\left(\mathrm{~N}\left(\lambda \pi_{\partial \mathrm{Q}}\left(\Pi \backslash \Pi_{-\nu}\right), \sqrt{\mathrm{d}}\right)\right)<\frac{\varepsilon}{8 \mathrm{~m}_{2}} \lambda^{\mathrm{d}-1}
$$

(b) Let $x \in \Pi$ and $\left\langle e, n_{x}\right\rangle \geq 1 /(2 \sqrt{d})$ for some $i \in\{1, \ldots, d\}$ and $q \in N$. Then there are positive $\omega_{2}, \lambda_{0}$ with the following property: For all $j \in\{1, \ldots, \mathrm{~d}\}, \mathrm{j} \neq \mathrm{i}$, all $\lambda>\lambda_{0}$, and all $\mathrm{Q} \in \mathcal{K}^{\mathrm{d}}$ with $\Delta^{\mathrm{H}}(\mathrm{M}, \mathrm{Q})<\omega_{2}$ there are simple $(\mathrm{i}, \mathrm{j})$-strips U , of length q , $I=1, \ldots, m(\lambda)$, such that $U=\bigcup U$, covers $\lambda \pi_{\partial Q}\left(\Pi_{-\nu}\right)$ and each $U$, is contained in $\pi_{\partial Q}\left(\Pi_{-\nu / 2}\right)$.

Proof The first statement is an immediate consequence of Lemma 3.1. Next observe that $\mathrm{W}(\mathrm{z}) \cap \lambda \partial \mathrm{Q}=\mathrm{W}(\mathrm{z}) \cap \lambda \pi_{\partial \mathrm{Q}}\left(\Pi_{-\nu / 2}\right)$ holdsfor every $\mathrm{z} \in \mathrm{Z}^{\mathrm{d}}$ with $\mathrm{W}(\mathrm{z}) \cap \lambda \pi_{\partial \mathrm{Q}}\left(\Pi_{-\nu}\right) \neq \varnothing$.

For each $\Pi$ we choose fixed $\mathrm{i}, \mathrm{j}, \mathrm{q}$ in Lemma 5.5 (b). For this choice we write $\Sigma(\Pi)=$ $\left\{z \in Z^{\mathrm{d}} \mid \mathrm{W}(z) \cap U \neq \varnothing\right\}$. We observe by our previous lemma that the sets $\Sigma(\Pi)$ are mutually disjoint.

In the sequel we must take into account the difference between Q and M and that we have only approximate normals of patches. Thus for given $\mathrm{P}_{\mathrm{i}}, \mathrm{v} \in \mathrm{P}_{\mathrm{ij}}, \mathrm{x} \in \mathrm{Q}$, and $\theta \geq 0$ we say that $\mathrm{v} \theta$-approximates Q at x if for $0 \leq \mu \leq 1$ there exists a $\tau(\mu)$ with $|\tau(\mu)| \leq \theta$ and $\mathrm{x}+\mu \mathrm{V}+\tau(\mu) \mathrm{e} \in \partial \mathrm{Q}$.

Let $\Pi$ be a fixed patch from Lemma 5.3 (b) and $\nu$ the number from Lemma 5.5. Let $\mathrm{x} \in \pi_{\partial \mathrm{Q}}\left(\Pi_{-\nu}\right)$ and $\mathrm{n}_{\mathrm{x}}$ a normal at x . We may assume that $\left|\left\langle\mathrm{e}_{1}, \mathrm{n}_{\mathrm{x}}\right\rangle\right|=\max \left\{\left|\left\langle e_{\mathrm{e}}, \mathrm{n}_{\mathrm{x}}\right\rangle\right|\right\} \geq$ $1 / \sqrt{d}$ and $P_{12}$ is the plane given by Lemma 4.2 for $n_{x}$. Let $u=\left(u_{1}, 1,0, \ldots, 0\right)$ be a support vector at x to $\mathrm{Q} \cap \mathrm{P}_{12}$. Let $\mathrm{n}_{0}$ be the number given in Lemma 4.1 for $\chi=\eta$, where $\eta$ is the angle used in the construction of the patches. We may assume that the conditions of Lemma 5.5 (b) are satisfied for $\mathrm{q}=\mathrm{n}_{0}$. Thus we have a lattice vector ( $\mathrm{m}, \mathrm{n}$ ) with $\mathrm{n} \leq \mathrm{n}_{0}$ such that $\angle(\mathrm{u},(\mathrm{m}, \mathrm{n})) \leq \eta$. By the choice of $\eta$ we have on the other hand by Lemma 4.2 that $\|(\mathrm{m}, \mathrm{n})\| \geq \phi$.

We now ascertain that nearly all strips on $\pi_{\partial \mathrm{Q}}$ (П) behave nicely: We may assume that $\Delta^{H}(\mathrm{Q}, \mathrm{M})$ is sufficiently small and $\lambda$ sufficiently large, that by Lemma $2.1 \angle\left(\mathrm{n}_{\mathrm{x}}, \mathrm{n}_{\mathrm{y}}\right) \leq 2 \eta$ for all $\mathrm{y} \in \pi_{\partial Q}\left(\Pi_{-\nu / 2}\right)$ and by Lemma $5.5 \lambda \pi_{\partial Q}\left(\Pi_{-\nu}\right)$ is covered by simple $(1,2)$-strips $\mathrm{U}_{\mathrm{j}}$ of length $n$ such that each $\mathrm{U}_{\mathrm{j}}$ is contained in $\pi_{\partial \mathrm{O}}\left(\mathrm{F}_{-\nu / 2}\right)$.

Let now $U_{j}$ be such a simple ( 1,2 )-strip at $z=\left(z_{1}+\alpha, z_{2}, \ldots, z_{d}\right)$ of length $n$. Let $\bar{z}=\left(z_{1}+\bar{\alpha}, z_{2}+(n-1) / 2, z_{3}, \ldots, z_{d}\right)$ such that $\bar{z} \in U_{j}$. Now for $-n / 2 \leq \mu \leq n / 2$ let $\mathrm{z}(\mu)$ be defined by the condition, that $\mathrm{z}(\mu)=\left(\mathrm{z}_{1}+\alpha(\mu), \mathrm{z}_{2}+\mu, \mathrm{z}_{3}, \ldots, \mathrm{z}_{\mathrm{d}}\right) \in \mathrm{U}_{\mathrm{j}}$. Then we have by our construction that $|z(\mu)-\bar{z}-\mu \mathrm{u}| \leq \mu / \mathrm{n}$ and $\left|\mu\left(\mathrm{u}-\left(\frac{m}{n}, 1\right)\right)\right| \leq \mu / \mathrm{n}$. Thus $(\mathrm{m}, \mathrm{n}) 1 / \mathrm{n}$-approximates Q at $\left(\mathrm{z}_{1}+\alpha, \mathrm{z}_{2}-1 / 2, \mathrm{z}_{3}, \ldots, \mathrm{z}_{\mathrm{d}}\right)$.

Therefore Lemma 5.1 and Lemma 2.4 yield

$$
\left|\sum_{i=0}^{n-1}\left(\sum_{z \in z_{i}, z \in \lambda Q} V(W(z) \backslash \lambda Q)-\sum_{z \in z_{i}, z \notin \lambda Q} V(W(z) \cap \lambda Q)\right)\right| \leq \frac{1}{2}+n \frac{\varepsilon}{5} .
$$

Since $n \geq \phi=5 / \varepsilon$, we deduce by adding up:
Lemma 5.6 Let $\Pi$ be a patch given by Lemma 5.3 (b). Then there exist $\nu, \omega, \lambda_{0}>0$ such that for $\Delta^{H}(Q, M) \leq \omega$ and $\lambda>\lambda_{0}$

$$
\left|\sum_{z \in \lambda Q, z \in \Sigma(\Pi)} V(W(z) \backslash \lambda Q)-\sum_{z \notin \lambda Q, z \in \Sigma(\Pi)} V(W(z) \cap \lambda Q)\right| \leq \frac{\varepsilon}{4} \cdot \mathcal{H}^{d-1}(\lambda \Pi) .
$$

Finally, we need some book keeping in order to prove Theorem B. We deduce by Lemma 5.4 (a) and Lemma 5.6 that the facets from Lemma 5.3 (a) and the patches from Lemma 5.3 (b) cause all together an error of at most $\frac{1}{2} \varepsilon \lambda^{d-1}$ (remember that $S(M)=1$ ). Now the error caused by the cubes which intersect the rest of $\lambda Q$ is at most $\frac{1}{2} \varepsilon \lambda^{d-1}$ by Lemma 5.3 (c), Lemma 5.4 (b) and Lemma 5.5 (a). Summing up these estimates completes the proof of Theorem B.

## 6 The $\mathbf{O}$ ptimality of the Estimates of Theorem B and Corollary C

We present series of examples to show that the estimates of Corollary $C$ and hence of Theorem $B$ are optimal in general. Again it is sufficient to consider the case $\Lambda=Z^{d}$.

First we look at the coefficient of $\lambda^{\mathrm{d}-1}$. Here we have optimality for all M.
Example 6.1 Theterm $S_{\Lambda}(M) \lambda^{d-1}$ is optimal in Corollary $C$ for any $M \in \mathcal{K}^{d}$.
As the statement is trivial if $\mathrm{S}_{Z^{d}}(M)=0$, we assume $\mathrm{S}_{Z^{d}}(M)>0$. Let $\varepsilon>0$, and we prove the existence of arbitrary large $\lambda$ so that

$$
\begin{equation*}
G(\lambda M)>V(M) \lambda^{d}+\frac{1}{2} S_{Z^{d}}(M) \lambda^{d-1}-\varepsilon \lambda^{d-1} \tag{14}
\end{equation*}
$$

Note that the optimality of the lower bound can be similarly proved, choosing $\lambda=q-\frac{1}{q^{1 / m}}$ in (c) below.

As in the proof of Theorem $B$, set $W(z)=z+\left[-\frac{1}{2}, \frac{1}{2}\right)$ and assume $S(M)=1$ and $0 \in \operatorname{int} M$. The proof of Theorem B shows that we may choose finitely many lattice facets with outer unit normals $u_{1}, \ldots, u_{m}$ such that
(a) $\frac{1}{2} \sum \frac{\mathcal{H}^{d-1}\left(F_{M}\left(u_{i}\right)\right)}{\operatorname{det}\left(u_{i}^{\perp} \cap Z^{d}\right)}>\frac{1}{2} S_{Z^{d}}(M)-\frac{\varepsilon}{4}$,
(b) for large $\lambda$ and $\Omega_{\lambda}=\left\{\mathrm{z} \mid \mathrm{W}(\mathrm{z}) \cap \lambda\left(\partial \mathrm{M} \backslash \bigcup \mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right)\right) \neq \varnothing\right\}$,

$$
\left|\sum_{z \in \Omega \cap \lambda M} V(W(z) \backslash M)-\sum_{z \in \Omega \backslash \lambda M} V(W(z) \cap M)\right|<\frac{\varepsilon}{4} \lambda^{d-1}
$$

Now observe that $\tau_{i}^{-1} \mathrm{~F}_{M}\left(\mathrm{u}_{\mathrm{i}}\right)$ is contained in some lattice hyperplane for $\tau_{\mathrm{i}}=$ $H_{M}\left(u_{i}\right) \operatorname{det}\left(u_{i}^{\perp} \cap Z^{d}\right)$. Applying simultaneous Diophantine approximation to $\tau_{1}, \ldots, \tau_{m}$ (compare the proof of Lemma 4.3) results in an arbitrarily large integer $q$ and corresponding $p_{1}, \ldots, p_{m} \in Z$ satisfying $\left|p_{i}-q \tau_{i}\right|<\frac{1}{q^{1 / m}}$, and hence

$$
\left|\frac{p_{i}}{\operatorname{det}\left(u_{i}^{\perp} \cap Z^{d}\right)}-q H_{M}\left(u_{i}\right)\right|<\frac{1}{q^{1 / m}}
$$

In particular, Lemma 5.1 yields for large $q$ and $i=1, \ldots, m$ that
(c) for $\lambda=\mathrm{q}+\frac{1}{\mathrm{q}^{1 / m}}$ and $\Omega_{\lambda}^{i}=\left\{\mathrm{z} \mid \mathrm{W}(\mathrm{z}) \cap \lambda \mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right) \neq \varnothing\right\}$,

$$
\sum_{z \in \Omega_{\lambda}^{i} \cap M} V(W(z) \backslash M)-\sum_{z \in \Omega_{\lambda}^{i} \backslash M} V(W(z) \cap M)>\frac{1}{2} \frac{\mathcal{F}^{d-1}\left(F_{M}\left(u_{i}\right)\right)}{\operatorname{det}\left(u_{i}^{\perp} \cap Z^{d}\right)} \lambda^{d-1}-\frac{\varepsilon}{4 m} \lambda^{d-1} .
$$

Since the number of fundamental cells intersecting the relative boundary of any of the $\mathrm{F}_{\mathrm{M}}\left(\mathrm{u}_{\mathrm{i}}\right)$ is $\mathrm{O}\left(\lambda^{\mathrm{d}-2}\right)$ (see the proof of Theorem A), combining (a), (b) and (c) yields (14) by the formula (8).

Next we look at the term o $\left(\lambda^{d-1}\right)$. Here we have

Example 6.2 The error term $\mathrm{o}\left(\lambda^{\mathrm{d}-1}\right)$ in Corollary C is optimal.
For sake of simplicity, we provide an example only for $d=2$ and $S_{Z^{2}}(M)=0$.
For our example we need the following well-known statement from the theory of numbers:

Lemma 6.3 Let $\left\{\delta_{q}\right\}$ be a sequence of positive numbers. Then thereexists a $\tau$ with $0<\tau<$ 1 such that for infinitely many pairs $(p, q)$ of relatively prime natural numbers we have

$$
0<\mathrm{p} \cdot \tau-\mathrm{q}<\delta_{\mathrm{q}}
$$

Proof The lemma is proved in a constructive way, completely analogously to the construction of "Liouville-type" transcendental numbers (see [Sc]).

Our examples are given explicitly in the next lemma:
Lemma 6.4 Let $\varepsilon: \mathrm{R}_{+} \rightarrow \mathrm{R}_{+}$be a function satisfying $\lim _{\lambda \rightarrow \infty} \varepsilon(\lambda)=0$. Then there exists an 0 -symmetric parallelogram $M$ with $S_{Z^{d}}(M)=0$ such that for any natural number $N$ there existsa $\lambda>N$ satisfying

$$
\begin{equation*}
|G(\lambda M)-V(\lambda M)|>\varepsilon(\lambda) \cdot S(\lambda M) \tag{15}
\end{equation*}
$$

Proof By replacing $\varepsilon(\lambda)$ by

$$
\sup \{\varepsilon(\mathrm{t}) \mid \mathrm{t} \geq \lambda\}
$$

we may assume that $\varepsilon(\lambda)$ is decreasing.
For $M \in \mathcal{K}^{2}$ we define for $\lambda>0$ and $0<I<1$ the function $f_{M}(\lambda, I)$ by

$$
f_{M}(\lambda, I)=\frac{G((\lambda+I) M)-G(\lambda M)-V((\lambda+I) M)+V(\lambda M)}{S(\lambda M)} .
$$

Now we assume that $M$ is given so that for any large $\lambda>0$,

$$
\begin{equation*}
|G(\lambda M)-V(\lambda M)| \leq \varepsilon(\lambda) \cdot S(\lambda M) \tag{16}
\end{equation*}
$$

For such an $M(16)$ and $\varepsilon(\lambda+I) \leq \varepsilon(\lambda)$ yield that for $\lambda>1$,

$$
\begin{equation*}
f_{M}(\lambda, l)<4 \cdot \varepsilon(\lambda) \tag{17}
\end{equation*}
$$

We prove the lemma by constructing a parallelogram M which does not satisfy (17) for certain pairs $(\lambda, I)$ where $\lambda$ can be arbitrarily large. For every positive integer q we choose a positive integer $m=m(q)$, so that

$$
4 \cdot \varepsilon(m \cdot q)<\frac{1}{q^{2}}
$$

and a $\delta_{\mathrm{q}}>0$ satisfying

$$
\begin{equation*}
\delta_{\mathrm{q}}<\frac{1}{\mathrm{~m} \cdot \mathrm{q}^{2}} \tag{18}
\end{equation*}
$$

Let $\tau$ bethe number provided by Lemma 6.3. We observe that $\tau$ is irrational.
Now we set $u=e_{1}+\tau \cdot e_{2}, v=\tau \cdot e_{1}-e_{2}$. Then the parallelogram $M$ is given by

$$
\mathrm{M}=\operatorname{conv}\{ \pm u \pm \mathrm{v}\} .
$$

We observe that the length of an edge of $M$ is between 2 and $2 \sqrt{2}$. We denote by $L$ the line through $o$ and u. Now let

$$
0<p \cdot \tau-q<\delta_{q}
$$

for relatively prime natural numbers $p, q$. We set $m=m(q)$ and $w=q e_{1}+p e_{2}$. For any integer $t$ with $|t| \leq 2 m$, the distance of tw from $L$ is at most $2 m \delta_{q}$. Thus for large $q$, we may choose $\lambda$ with

$$
m \cdot q<\lambda<m \cdot q+1,
$$

so that each edge of $\lambda M$ contains one lattice point, and there exist 2 m lattice points along each side of $\lambda M$ which are not in that square but the distance of these points from $\lambda M$ is at most $2 \mathrm{~m} \delta_{q}$. Let I be minimal so that all of these $4 \times 2 \mathrm{~m}$ points are contained in $(\lambda+\mathrm{I}) \mathrm{M}$.

It is easy to see that

$$
\begin{gathered}
G((\lambda+I) M)-G(\lambda M)>c_{1} \cdot m, \\
V((\lambda+I) M)-V(\lambda M)<c_{2} \cdot m^{2} \cdot q \cdot \delta_{q},
\end{gathered}
$$

and finally,

$$
S(\lambda M)<c_{3} \cdot m \cdot q
$$

for fixed positive $\mathrm{c}_{\mathrm{i}}, \mathrm{i}=1,2,3$. $\operatorname{Now} \varepsilon(\lambda) \leq \varepsilon(\mathrm{mq})$, and the definition of $\mathrm{m}(\mathrm{q})$ and $\delta_{\mathrm{q}}$ yield that if $q$ is chosen large enough then

$$
f_{M}(\lambda, I)>\frac{c_{1}}{2 c_{3}} \cdot \frac{1}{q}>4 \cdot \varepsilon(\lambda)
$$

Therefore the lemma follows by (17).
For a higher dimensional example, one can use a parallelotope such that all but two coordinates of each facet normal are zero, and the two non-zero coordinates are 1 and the $\tau$ above. In order to ensure $\mathrm{S}_{\mathbb{Z}^{\mathrm{d}}}(\mathrm{M})>0$, one just cuts the parallelotope by a lattice hyperplane.

Finally we remark that even under the additional assumption of differentiability, we can not hope to improve our estimates very much as Theorem 1 in [MN] shows that in the planar case $o(\lambda)$ cannot be replaced by $o\left(\lambda^{1-\varepsilon}\right)$ even if the boundary of $M$ is assumed to be analytical.

## 7 Number of Lattice Points in Large Bodies

We deduce by (5) that

$$
d \cdot V(M, K ; 1) \geq \sum_{u \in \Lambda^{*} \text { prim. }} \frac{H_{K}(u)}{\|u\|} \cdot \mathcal{H}^{d-1}\left(F_{M}(u)\right) .
$$

It follows that if $\mathrm{H}_{\mathrm{K}}(\mathrm{u}) \geq 1 / 2$ for any primitive $\mathrm{u} \in \Lambda^{*}$ then

$$
\frac{\operatorname{det} \Lambda}{2} \cdot S_{\Lambda}(M) \leq d \cdot V(M, K ; 1) .
$$

SinceV ( $\cdot, \mathrm{K} ; 1$ ) is continuous, Theorem $B$ yields
Lemma 7.1 Let $\Lambda$ be a lattice in $\mathrm{E}^{d}$ and assume that for some $\mathrm{K} \in \mathcal{K}^{d}, \mathrm{H}_{\mathrm{K}}(\mathrm{u}) \geq 1 / 2$ for any primitive $u \in \Lambda^{*}$. If $M \in \mathscr{K}^{d}$ and $\left\{\mathrm{P}_{\lambda}\right\}$ is a family of convex bodies such that $\mathrm{P}_{\lambda} / \lambda$ tends to $M$ then

$$
\left|\operatorname{det} \Lambda \cdot G_{\Lambda}\left(P_{\lambda}\right)-V\left(P_{\lambda}\right)\right| \leq \operatorname{dV}\left(P_{\lambda}, K ; 1\right)+o\left(S\left(P_{\lambda}\right)\right) .
$$

Theorem D generalizes this statement to the case where the only condition is that the inradius of the $P_{\lambda}$ tends to infinity. As we frequently need the volume of lower dimensional convex bodies we write $|\mathrm{K}|$ rather than $\mathcal{H}^{\text {dim }}(\mathrm{K})$.

Proof of Theorem D As for Theorem B we observe that the inequality in Theorem D is invariant with respect to simultaneous nondegenerate linear transformations of $\Lambda, K$ and the $\mathrm{P}_{\lambda}$. Thus we may assume that $\Lambda=Z^{\text {d }}$. Further approximating $\mathrm{P}_{\lambda}$ by polytopes with the same number of lattice points shows that it is sufficient to consider the case where all $P_{\lambda}$ are polytopes. We do this by induction on $d$ where the case $d=1$ is trivial. So we assume that the theorem holds for all dimensions less than $\mathrm{d}, \mathrm{d} \geq 2$. In addition, we assume that contradicting our statement, there exist an $\varepsilon>0$ and a sequence $\left\{\mathrm{P}_{\lambda}\right\}$ of polytopes with $\mathrm{r}_{\mathrm{d}}\left(\mathrm{P}_{\lambda}\right) \rightarrow \infty$ for $\lambda \rightarrow \infty$ and

$$
\begin{equation*}
\left|G\left(P_{\lambda}\right)-V\left(P_{\lambda}\right)\right| \geq d V\left(P_{\lambda}, K ; 1\right)+\varepsilon \cdot S\left(P_{\lambda}\right) . \tag{19}
\end{equation*}
$$

If $R\left(P_{\lambda}\right) / r_{d}\left(P_{\lambda}\right)$ is bounded then by possibly taking a suitable subsequence, we may assume that $P_{\lambda} / r_{d}\left(P_{\lambda}\right)$ tends to some convex body $M$. Then $S\left(P_{\lambda}\right) \sim S\left(r_{d}\left(P_{\lambda}\right) M\right)$, and hence we easily obtain a family based on $\left\{\mathrm{P}_{\lambda}\right\}$ contradicting Lemma 7.1. So we may assume that for some $1 \leq \mathrm{k} \leq \mathrm{d}-1$ and $\mathrm{c}>0$, we have $\mathrm{r}_{\mathrm{k}+1}\left(\mathrm{P}_{\lambda}\right)<\mathrm{c} \cdot \mathrm{r}_{\mathrm{d}}\left(\mathrm{P}_{\lambda}\right)$ but $\mathrm{r}_{\mathrm{k}}\left(\mathrm{P}_{\lambda}\right) / \mathrm{r}_{\mathrm{k}+1}\left(\mathrm{P}_{\lambda}\right)$ tends to infinity.

Let $L_{\lambda}$ a best approximating affine $k$-plane for $P_{\lambda}$ (cf. Section 2). By taking a suitable subsequence, we may assume that the linear $k$-planes $L_{\lambda}-L_{\lambda}$ tend to a linear $k$-planeL̃.

In the following $z$ always denotes a point of $Z^{\mathrm{d}}$. The main idea of theinductive step is as follows: We choose a lattice $k$-plane L close to L , and a semi-open fundamental cell T for $L \cap Z^{d}$. We define a tiling $W(z), z \in Z^{d}$, where each $W(z)$ is congruent to $T+T_{0}$ and $T_{0}$ is a semi-open fundamental cell for $\pi_{\llcorner\perp}\left(Z^{\mathrm{d}}\right)$. We have in analogy to formula (8)

$$
\begin{equation*}
G\left(P_{\lambda}\right)-V\left(P_{\lambda}\right)=\sum_{\substack{z \in Z^{d} \cap P_{\lambda} \\ W(z) \cap P_{\lambda} \neq \varnothing}} V\left(W(z) \backslash P_{\lambda}\right)-\sum_{\substack{z \in Z^{d} \backslash P_{\lambda} \\ W(z) \cap \cap} \neq \varnothing} N(W(z) \cap P) . \tag{20}
\end{equation*}
$$

Thus it is sufficient to consider tiles around the boundary of $P_{\lambda}$. We split up $P_{\lambda}$ into pieces $\left(z+T+L^{\perp}\right) \cap P_{\lambda}$. For large $\lambda$ most of the pieces are almost orthogonal prisms with a basis of the form $\left(z+L^{\perp}\right) \cap P_{\lambda}$. Splitting up the summation with respect to the pieces and projecting on $\mathrm{L}^{\perp}$ will give a counterexample in $\mathrm{L}^{\perp}$ which contradicts the inductive hypothesis.

For every k -plane L we have for $\mathrm{D}=\pi_{\mathrm{L} \perp}(\mathrm{K})$ that $\mathrm{H}_{\mathrm{K}}(\mathrm{u})=\mathrm{H}_{\mathrm{D}}(\mathrm{u})$ for all u satisfying $\left\|\pi_{\mathrm{L}}(\mathrm{u})\right\|=0$. Thus by Lemma 4.3 for every $\delta>0$ there is a lattice $k$-plane $L$ with the following properties.
(a) There exists a $M$ inkowski reduced basis $\mathrm{w}_{1}, \ldots, \mathrm{w}_{\mathrm{k}}$ of $\mathrm{L} \cap \mathrm{Z}^{\mathrm{d}}$ such that the distance of any point of

$$
\mathrm{T}=\left\{\sum_{\mathrm{i}=1}^{\mathrm{k}} \alpha_{\mathrm{i}} \mathrm{w}_{\mathrm{i}} \mid 0 \leq \alpha_{\mathrm{i}}<1\right\}
$$

from $\tilde{L}$ is at most $\delta$.
(b) There exists an $\varepsilon_{0}>0$ such that for $\lambda$ sufficiently large and $\left\|\pi_{L_{\lambda}}(\mathrm{u})\right\|<\varepsilon_{0}$

$$
\begin{equation*}
\left|H_{\mathrm{K}}(\mathrm{u})-\mathrm{H}_{\mathrm{D}}(\mathrm{u})\right|<\delta \tag{21}
\end{equation*}
$$

holds.
Next let $w_{k+1}, \ldots, w_{d}$ be a basis of $\pi_{\llcorner\perp}\left(Z^{\mathrm{d}}\right)$, and define

$$
\mathrm{W}=\left\{\sum_{\mathrm{i}=1}^{\mathrm{d}} \alpha_{\mathrm{i}} \mathrm{w}_{\mathrm{i}} \mid 0 \leq \alpha_{\mathrm{i}}<1\right\} .
$$

For $a z \in Z^{d}$, consider the $y \in Z^{d} \cap L$ satisfying $\pi_{\llcorner }(z) \in y+T$, and set

$$
\mathrm{W}(\mathrm{z})=\pi_{\mathrm{L} \perp}(\mathrm{z})+\mathrm{y}+\mathrm{W} .
$$

Then $\{W(z)\}, z \in Z^{d}$ is atiling of $\mathrm{E}^{\mathrm{d}}$.
In the next step we split up the summation in (20). First we identify the "bad" part and show that it is not too large. To do this we define

$$
\omega_{\lambda}=\max \left\{\frac{1}{\sqrt{r_{d}(P)}}, \sqrt{\frac{r_{k+1}\left(P_{\lambda}\right)}{r_{k}\left(P_{\lambda}\right)}}\right\}
$$

and $M(\omega)=\pi L_{\lambda}\left((1-\omega) P_{\lambda}\right)+\omega c\left(\pi_{L_{\lambda}}\left(P_{\lambda}\right)\right)$ (cf. Section 2). The union of all $W(z)$, which intersect $\partial \mathrm{P}_{\lambda}$ and are not contained in $\mathrm{M}\left(\omega_{\lambda}\right)+\mathrm{L}^{\perp}$, is denoted by $\mathrm{N}_{\lambda}$. We have for suitable $\mathrm{t}>0$ that

$$
N_{\lambda} \subset N\left(\partial P \cap\left(\left(\pi_{L_{\lambda}}\left(P_{\lambda}\right) \backslash M\left(\omega_{\lambda}\right)\right)+L^{\perp}\right), t\right) .
$$

We deduce by the definition of $\omega_{\lambda}$ and Lemma 2.8 (a) that

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \frac{r_{k+1}\left(P_{\lambda}\right)}{\omega_{\lambda} \cdot r_{k}\left(\pi_{L_{\lambda}}\left(P_{\lambda}\right)\right)}=0 \tag{22}
\end{equation*}
$$

which in turn yields by Lemma 2.9 that

$$
\begin{equation*}
\lim _{\lambda \rightarrow \infty} \frac{\mathrm{V}\left(\mathrm{~N}_{\lambda}\right)}{\mathrm{S}\left(\mathrm{P}_{\lambda}\right)}=0 \tag{23}
\end{equation*}
$$

We set $\Omega_{\lambda}=Z^{\mathrm{d}} \cap \mathrm{L} \cap\left(\mathrm{M}\left(\omega_{\lambda}\right)+\mathrm{L}^{\perp}\right)$. Now (20) and (23) yield that

$$
G\left(P_{\lambda}\right)-V\left(P_{\lambda}\right)=\sum_{z \in \Omega_{\lambda}} G\left(\left(z+T+L^{\perp}\right) \cap P_{\lambda}\right)
$$

$$
\begin{equation*}
-\sum_{z \in \Omega_{\lambda}} V\left(\left(z+T+L^{\perp}\right) \cap P_{\lambda}\right)+o\left(S\left(P_{\lambda}\right)\right) \tag{24}
\end{equation*}
$$

For large $\lambda$, we have

$$
\begin{equation*}
\pi_{\mathrm{L}_{\lambda}}\left(\mathrm{P}_{\lambda}\right) \backslash \mathrm{M}\left(\frac{1}{2} \omega_{\lambda}\right) \subset \pi_{\mathrm{L}_{\lambda}}\left(\mathrm{N}_{\lambda}\right) \tag{25}
\end{equation*}
$$

by (22). Let $x \in \partial P_{\lambda} \subset L_{\lambda}+(k+1) r_{k+1}\left(P_{\lambda}\right) B^{d}$ such that $\pi_{L_{\lambda}}(x)=y \in M\left(\frac{1}{2} \omega_{\lambda}\right)$. Thek-ball in $L_{\lambda}$ centered at $y$ with radius $\frac{1}{2} \omega_{\lambda} r_{k}\left(P_{\lambda}\right)$ is contained in $\pi_{L_{\lambda}}\left(P_{\lambda}\right)$, and henceif $u_{x}$ is an unit outer normal at $x$ then

$$
\begin{equation*}
\left\|\pi_{L_{\lambda}}\left(u_{\mathrm{x}}\right)\right\|<\mathrm{c} \cdot \frac{\mathrm{r}_{\mathrm{k}+1}\left(\mathrm{P}_{\lambda}\right)}{\omega_{\lambda} \cdot r_{\mathrm{k}}\left(\mathrm{P}_{\lambda}\right)} \tag{26}
\end{equation*}
$$

On the other hand, Lemma 2.9 implies that if $n_{x}$ is some unit outer normal at $x \in \partial P_{\lambda}$ then

$$
\begin{equation*}
d V\left(P_{\lambda}, K ; 1\right)=\int_{\bigcup_{z \in \Omega_{\lambda}}\left(z+T+L_{0}\right) \cap \partial P_{\lambda}} H_{K}\left(n_{x}\right) d x+0\left(S\left(P_{\lambda}\right)\right) \tag{27}
\end{equation*}
$$

Now we make use of the estimates, how well $L$ approximates $L_{\lambda}$ for large $\lambda$. For $z \in \Omega_{\lambda}$, let $A_{\lambda}(z) \subset L^{\perp}$ be the maximal and $C_{\lambda}(z) \subset L^{\perp}$ be the minimal convex, compact set such that

$$
\mathrm{z}+\mathrm{T}+\mathrm{A}_{\lambda}(\mathrm{z}) \subset\left(\mathrm{z}+\mathrm{T}+\mathrm{L}^{\perp}\right) \cap \mathrm{P}_{\lambda} \subset \mathrm{z}+\mathrm{T}+\mathrm{C}_{\lambda}(\mathrm{z})
$$

Denote by $\mathrm{v}(\cdot)$ the volumes or mixed volumes in $L^{\perp}$, and by $\mathrm{s}(\cdot)$ the surface area in $\mathrm{L}^{\perp}$.
We observe that by the construction of T for sufficiently small $\delta$ and sufficiently large $\lambda$

$$
|\mathrm{T}| \mathrm{V}\left(\mathrm{~A}_{\lambda}(\mathrm{z})\right) \leq \mathrm{V}\left(\left(\mathrm{z}+\mathrm{T}+\mathrm{L}^{\perp}\right) \cap \mathrm{P}_{\lambda}\right) \leq|\mathrm{T}| \mathrm{V}\left(\mathrm{C}_{\lambda}(\mathrm{z})\right) \leq|\mathrm{T}|\left(\mathrm{v}\left(\mathrm{~A}_{\lambda}(\mathrm{z})\right)+\frac{\varepsilon}{4}\right)
$$

Writing $P_{\lambda}(y)=\left(y+L^{\perp}\right) \cap P_{\lambda}$ for $y \in L$ we have further for $B_{\lambda}(z)=A_{\lambda}(z)$ or $B_{\lambda}(z)=$ $C_{\lambda}(z)$,

$$
\begin{aligned}
& \left|\int_{(z+T+L+) \cap \partial P_{\lambda}} H_{k}\left(u_{x}\right) d x-|T|(d-k) v\left(B_{\lambda}(z), D ; 1\right)\right| \\
& \quad \leq\left|\int_{T} \int_{(z+y+L+) \cap \partial P_{\lambda}} H_{D}\left(u_{x}\right) d x d y-|T|(d-k) v\left(B_{\lambda}(z), D ; 1\right)\right|+\frac{\varepsilon}{8}|T| s\left(B_{\lambda}(z)\right) \\
& \quad=\left|(d-k) \int_{T} v\left(P_{\lambda}(z+y), D ; 1\right) d y-|T| v\left(B_{\lambda}(z), D ; 1\right)\right|+\frac{\varepsilon}{8}|T| s\left(B_{\lambda}(z)\right) \\
& \quad \leq \frac{\varepsilon}{4}|T| s\left(B_{\lambda}(z)\right) .
\end{aligned}
$$

Therefore(19) yields for large $\lambda$ by (21), (24) and (27) that either

$$
\begin{align*}
& \sum_{z \in \Omega_{\lambda}} G\left(T+A_{\lambda}(z)\right)  \tag{28}\\
& \quad \leq|T| \cdot \sum_{x \in \Omega_{\lambda}} v\left(A_{\lambda}(z)\right)-|T| \cdot \sum_{x \in \Omega_{\lambda}}\left[(d-k) \cdot v\left(A_{\lambda}(z), D ; 1\right)+\frac{\varepsilon}{4} \cdot s\left(A_{\lambda}(z)\right)\right]
\end{align*}
$$

or

$$
\begin{align*}
& \sum_{z \in \Omega_{\lambda}} G\left(T+C_{\lambda}(z)\right) \\
& \quad \geq|T| \cdot \sum_{x \in \Omega_{\lambda}} v\left(C_{\lambda}(z)\right)+|T| \cdot \sum_{x \in \Omega_{\lambda}}\left[(d-k) \cdot v\left(C_{\lambda}(z), D ; 1\right)+\frac{\varepsilon}{4} \cdot s\left(C_{\lambda}(z)\right)\right] . \tag{29}
\end{align*}
$$

Wedenoteby $\Lambda^{\prime}$ theorthogonal projection of $Z^{\mathrm{d}}$ onto $L^{\perp}$ and notethat $\operatorname{det} Z^{\mathrm{d}}=\operatorname{det} \Lambda^{\prime}$. $|\mathrm{T}|$ and for any $\sigma \subset \mathrm{L}^{\perp}$, we have $\mathrm{G}(\sigma+\mathrm{T})=\mathrm{G}_{\Lambda^{\prime}}(\sigma)$. We deduce by (28) and (29) that for any large $\lambda$ there exists an $z \in \Omega_{\lambda}$ such that for $A_{\lambda}=A_{\lambda}(z)$ and $C_{\lambda}=C_{\lambda}(z)$, either

$$
\operatorname{det} \Lambda^{\prime} \cdot G_{\Lambda^{\prime}}\left(A_{\lambda}\right) \leq v\left(A_{\lambda}\right)-(d-k) \cdot v\left(A_{\lambda}, D ; 1\right)-\frac{\varepsilon}{4} \cdot s\left(A_{\lambda}\right)
$$

or

$$
\operatorname{det} \Lambda^{\prime} \cdot G_{\Lambda^{\prime}}\left(C_{\lambda}\right) \geq v\left(C_{\lambda}\right)+(d-k) \cdot v\left(C_{\lambda}, D ; 1\right)+\frac{\varepsilon}{4} \cdot s\left(C_{\lambda}\right)
$$

Finally, $\omega_{\lambda} \cdot r_{d}\left(P_{\lambda}\right) \rightarrow \infty$ yields that $r_{d-k}\left(A_{\lambda}\right) \rightarrow \infty$. On the other hand, for any primitive u from the dual of $\Lambda^{\prime}$ in $L^{\perp}$, the relation $H_{D}(u) \geq 1 / 2$ readily holds. This contradiction with the induction hypothesis implies the theorem.

Remark 1 Assume that $K \in \mathcal{K}^{d}$ is minimal with the property that $H_{K}(v) \geq 1 / 2$ for any primitive $v \in \Lambda^{*}$. Then there exists some lattice d-polytope $P$ such that for the primitive outer facet normals $\mathrm{v}_{1}, \ldots, \mathrm{v}_{\mathrm{k}} \in \Lambda^{*}$ the formula $\mathrm{H}_{\mathrm{k}}\left(\mathrm{v}_{\mathrm{i}}\right)=1 / 2$ holds. Set $\mathrm{P}_{\lambda}=\lambda \mathrm{P}$ for $\lambda \in \mathrm{N}$. We deduce by Ehrhart's formula that

$$
\operatorname{det} \Lambda \cdot G_{\Lambda}\left(P_{\lambda}\right)=V\left(P_{\lambda}\right)+d V\left(P_{\lambda}, K ; 1\right)+0\left(\lambda^{d-2}\right)
$$

and hence Theorem D can not beimproved in general.
Remark 2 Assume that $\Lambda=Z^{d}$ and $K=\left[-\frac{1}{2}, \frac{1}{2}\right]^{d}$. Choosing $P_{\lambda}=\left[0, \mu_{\lambda}\right]^{d-1} \times[0, \lambda]$ where $\mu_{\lambda}$ tends arbitrarily slowly to infinity shows that the error term is optimal also in Theorem D.

Acknowledgement We would like to thank Volker Arhelger and Martin Henk for many helpful comments.
