Upper and lower bounds are obtained for the left tail of the normed limit $W_0$ of a supercritical branching process with varying environment, that is, for $P(W_0 < x)$ for small $x$. Two types of process are dealt with—Böttcher type and Schröder type—which between them cover "most" processes with zero extinction probability.

1. INTRODUCTION

A single-type branching process in a varying environment generalises the classical branching process (or Galton-Watson process), in that the number of offspring born to any individual depends on that individual's generation. Let the offspring distribution of an individual at time $n$ be given by the law of $X_n \quad n = 0, 1, 2, \ldots$

and denote by $Z_{m,n} \quad n = m, m+1, m+2, \ldots$

the total number of descendants at time $n$ of a single parent at time $m$. Let $\mu_n = E X_n$, then $\mu_{m,n} := \prod_{k=m}^{n-1} \mu_k = E Z_{m,n}$. We shall assume the $\mu_n$ are finite throughout. Put $W_{m,n} = Z_{m,n}/\mu_{m,n}$.

The following results are well known:

**Theorem 1.** (Almost surely convergence. Fearn [11], Jagers [15].) $\{W_{m,n}\}_{n=m}^{\infty}$ is a non-negative martingale with respect to the filtration $\{\mathcal{F}_m\}_{n=m}^{\infty}$, where $\mathcal{F}_m$ is the $\sigma$-algebra generated by $\{Z_{m,m}, Z_{m,m+1}, \ldots, Z_{m,n}\}$. Thus the $W_{m,n}$ converge almost surely to a random variable $W_m$ with $E W_m \leq 1$.

**Theorem 2.** ($L^2$ convergence. Fearn [11], Jagers [15].) Suppose that $v_n := \text{Var}(X_n/\mu_n)$ exists and is finite for all $n$. Then if

$$\sum_{k=m}^{\infty} \frac{v_k}{\mu_{m,k}} < \infty$$

499
then $W_{m,n} \xrightarrow{L^2} W_m$ and hence $\mathbb{E} W_m = 1$.

Note that $\text{Var} \ W_{m,n} = \sum_{k=m}^{n-1} v_k / \mu_{m,k}$, so (1) is equivalent to

$$\lim_{n \to \infty} \text{Var} \ W_{m,n} < \infty.$$ 

Moreover, it follows that $\text{Var} \ W_m$ exists and equals $\sum_{k=m}^{\infty} v_k / \mu_{m,k}$.

More recently, D’Souza and Biggins [8] have provided a generalisation of one half of the classic result of Kesten and Stigum [16]. Say the process $Z_{m,n}$ (for fixed $m$) is uniformly supercritical if there exist constants $A > 0$ and $c > 1$ such that for all $n \geq m$

$$\mu_{m,n} \geq Ac^{n-m}.$$ 

Also, say that the random variable $X$ dominates $Y$ if for all $x$

$$\Pr(Y > x) \leq \Pr(X > x).$$

Given these definitions we have:

**Theorem 3.** (Single growth rate. D’Souza and Biggins [8].) If the process $Z_{m,n}$ is uniformly supercritical and $X_n/\mu_n$ is dominated by some $X$ for all $n \geq m$, where

$$\mathbb{E} X \log^+ X < \infty,$$

then $\mathbb{E} W_m = 1$ and $\{W_m > 0\} = \{Z_{m,n} \to \infty\}$ almost surely.

Note that the conditions of Theorem 2 are not sufficient to give $\{W_m > 0\} = \{Z_{m,n} \to \infty\}$ almost surely, as is shown by the example of MacPhee and Schuh [17]. In particular, the conditions of Theorem 2 do not imply those of Theorem 3. (A simple condition, sufficient to imply the conditions of both Theorems 2 and 3, is that $1 < \mu := \liminf_n \mu_n$; $\bar{\mu} := \sup_n \mu_n < \infty$ and $\bar{v} := \sup_n v_n < \infty$. A suitable dominating random variable in this case is given by $X$ with density $2k^2x^{-3}$ on $[k, \infty)$, where $k^2 > \bar{v} + \bar{\mu}^2$.) Conditions for $\mathbb{E} W_m = 1$, strictly weaker than those of Theorem 3, are given by Goettge [12]. However, these are again insufficient to give a single rate of growth, as is shown in D’Souza and Biggins [8, Section 4]. Moreover, when $Z_{m,n}$ is uniformly supercritical, Goettge’s conditions are in practice the same as those of D’Souza and Biggins. See Goettge’s Theorems 5 and 7 and Example 9.

For the classical branching process we have $X_n = X$ for all $n$, and so $W_m = W$ for all $m$. Analysis of $W$ has distinguished two cases. We call the branching process Schröder if $\Pr(X = 0) = 0$ and $\Pr(X = 1) > 0$, and Böttcher if $\Pr(X = 0) =$
$P(X = 1) = 0$. In each case there is a single parameter which describes the asymptotic
distribution of $W$ at the origin. Put $\mu = \mathbb{E}X$, then in the Schröder case we have,
putting $p_1 = P(X = 1)$
$$\alpha = \frac{-\log p_1}{\log \mu}$$
and for the Böttcher case, putting $a = \min\{k : P(X = k) > 0\}$
$$\gamma = \frac{\log a}{\log \mu}.$$  

In the Schröder case Dubuc [9, 10] obtained the following algebraic bounds on the law
of $W$: for all $0 \leq x \leq x_0$ (some $x_0 > 0$)
$$c_1 x^\alpha \leq P(W < x) \leq c_2 x^\alpha.$$  
(Dubuc in fact gives bounds on the density of $W$. Integrating these gives the bounds on
the law of $W$ referred to.) In the Böttcher case Dubuc [10] and Bingham [7] obtained
the following exponential bounds: for all $x \geq 0$
$$c_3 \exp\{-c_4 x^{-\gamma/(1-\gamma)}\} \leq P(W < x) \leq c_5 \exp\{-c_6 x^{-\gamma/(1-\gamma)}\}.$$  
Here $c_1, \ldots, c_5$ are positive constants. Analogous results for the random environment
case have been proved by Hambly [13]. In what follows we generalise these results to
branching processes with varying environments. That is, we construct upper and lower
bounds for the left tail of $W_m$. The same two cases appear. Accordingly, say $Z_{m,n}$ is of
Schröder type if $X_n$ is Schröder for all $n \geq m$ and of Böttcher type if $X_n$ is Böttcher
for all $n \geq m$. Our results appear as Propositions 6 and 9 for the Böttcher case and as
Propositions 12 and 14 for the Schröder case.

We shall take as our basic assumptions:

C1 $\bar{\mu} := \sup_n \mu_n < \infty$.

C2 $Z_{0,n}$ is uniformly supercritical.

C3 All the $X_n/\mu_n$ are dominated by some $X$ with $\mathbb{E}X \log^+ X < \infty$.

Conditions C2 and C3 are the conditions of Theorem 3. Trivially, C2 is always satisfied
in the Böttcher case. In both the Schröder and Böttcher cases, the upper bounds we
find have in common with Theorem 3 a fundamental lemma, which uses the uniform
moment condition C3: see Lemma 4 below and Proposition 2 of D'Souza and Biggins
[8]. Our lower bounds do not use Theorem 3 directly, though they do require $\mathbb{E}W_m = 1$.
However, as we shall be assuming uniform supercriticality, this condition is (given
current technology) essentially the same as C3.
Condition C1 can be thought of as complementing C2.

The initial motivation for this work came from the study of diffusions on fractals. It turns out that in many cases a diffusion can be constructed on a fractal using a "nested" sequence of random walks, which has associated with it a branching process. Bounds on the law of the normed limit of this branching process translate directly into sample path results for the corresponding diffusion, and so are of some interest. For a review of the literature in this area see Barlow [1, 2]. In addition, these branching processes exhibit near-constancy phenomena in the limit. A number of results in this area have been given by Biggins and Bingham [4, 5]. These involve (amongst other things) bounds on both the left and right tails, though under different assumptions, providing generalisations of the above results for the classical branching process. Hambly [14] is also of interest in this context, as it gives an explicit calculation of the density of \( W \) in a special case.

The methods we use owe much to those of Hambly [13] and are similar to the arguments used by Barlow and Bass [3, Lemma 4.4].

2. PRELIMINARIES

For \( t \in [0,1] \), let \( f_n(t) = \mathbb{E} t^{X_n} \) be the probability generating function of \( X_n \) and \( f_{m,n}(t) = \mathbb{E} t^{Z_{m,n}} \) the probability generating function of \( Z_{m,n} \), then conditioning on \( Z_{m,m+1} \)

\[
f_{m,n}(t) = f_{m}(f_{m+1,n}(t)) = f_m(f_{m+1}(\cdots (f_{n-1}(t)) \cdots)).
\]

(2)

For \( u \in \mathbb{R}^+ \), write \( \varphi_{m,n}(u) = \mathbb{E} e^{-uW_{m,n}} \) for the Laplace transform of \( W_{m,n} \) and \( \varphi_m(u) = \mathbb{E} e^{-uW_m} \) for the Laplace transform of \( W_m \), then as \( W_{m,n} \xrightarrow{a.s.} W_m \), \( \varphi_{m,n}(u) \to \varphi_m(u) \). Moreover from (2), putting \( t = e^{-u/\mu_{m,p}} \) in \( f_{m,p}(t) \), we get

\[
\varphi_{m,p}(u) = f_{m,n}(\varphi_{n,p}(u/\mu_{m,n}))
\]

and so letting \( p \to \infty \)

\[
\varphi_m(u) = f_{m,n}(\varphi_n(u/\mu_{m,n})).
\]

(3)

Let \( p_i^n = P(X_n = i) \), \( p_i^{m,n} = P(Z_{m,n} = i) \), \( a_n = \inf\{i : p_i^n > 0\} \) and \( a_{m,n} = \inf\{i : p_i^{m,n} > 0\} = \prod_{k=m}^{n-1} a_k \). Then

\[
f_{m,n}(t) = \sum_{i=a_{m,n}}^{\infty} p_i^{m,n} t^i = t^{a_{m,n}} \sum_{i=a_{m,n}}^{\infty} p_i^{m,n} t^{i-a_{m,n}}
\]
whence, as \( \sum_{i=0}^{\infty} p_{i,m,n} t^{i-a_{m,n}} \leq 1 \) (as it is a probability generating function)

\[
(4) \quad p_{i,m,n} t^{i-a_{m,n}} \leq f_{m,n}(t) \leq t^{a_{m,n}}.
\]

Substituting (3) into (4) gives for all \( n \geq m \geq 0 \)

\[
(5) \quad p_{i,m,n} \varphi_n(u/\mu_{m,n})^{a_{m,n}} \leq \varphi_m(u) \leq \varphi_n(u/\mu_{m,n})^{a_{m,n}}.
\]

This inequality is the foundation upon which our results rest.

3. BÖTTCHER CASE

We shall assume throughout this section that \( Z_{0,n} \) is Böttcher. The varying environment analogue to \( \gamma \) is given by two parameters. For any \( m \geq 0 \) define

\[
\gamma^- := \liminf_{n \to \infty} \frac{\log a_{m,n}}{\log \mu_{m,n}} \quad \text{and} \quad \gamma^+ := \limsup_{n \to \infty} \frac{\log a_{m,n}}{\log \mu_{m,n}}.
\]

It is easily checked that \( \gamma^- \) and \( \gamma^+ \) do not depend on \( m \), and that

\[
\liminf_{n \to \infty} \frac{\log a_n}{\log \mu_n} \leq \gamma^- \leq \gamma^+ \leq \limsup_{n \to \infty} \frac{\log a_n}{\log \mu_n}.
\]

Also note that it is possible to have \( \gamma^- < \gamma^+ \). We shall write

\[
\gamma^+_\varepsilon \quad \text{for} \quad \gamma^+ + \varepsilon \quad \text{and} \quad \gamma^-_\varepsilon \quad \text{for} \quad \gamma^- - \varepsilon.
\]

Observe that C1 implies \( \gamma^- > 0 \). However, to guarantee \( \gamma^+ < 1 \) will require further conditions.

3.1 UPPER BOUND.

An upper bound on the law of \( W_0 \) is obtained from an upper bound on \( \varphi_0 \). To bound \( \varphi_0 \) we firstly get a uniform bound on all the \( \varphi_n \) near 0, and then apply (5) to these, to extend the bound on \( \varphi_0 \) out to infinity. (Hambly [13, Section 3] gives some discussion of the reasoning behind this approach.)

**Lemma 4.** (Uniform upper bound for all \( \varphi_n \)) Suppose C2 and C3 hold, then for any \( u_0 > 0 \) there exists a \( \beta < 1 \) such that for all \( n \)

\[
(6) \quad \varphi_n(u) \leq \beta \quad \text{for all} \quad u \geq u_0.
\]

**Proof:** Condition C2 gives us constants \( A > 0 \) and \( c > 1 \) such that \( \mu_{0,n} \geq A c^n \) for all \( n \geq 0 \). From Proposition 2 of D’Souza and Biggins [8] there exists a \( \theta_0 > 0 \) such that for all \( 0 \leq \theta \leq A \theta_0 \)

\[
\varphi_n(\theta) \leq e^{-\theta} + \theta r(\theta) + \frac{\theta}{\log c} \int_0^{\theta/A} \frac{r(\omega)}{\omega} \, d\omega
\]
where, if $X$ is the dominating random variable from Condition C3

$$r(\theta) = \frac{1}{\theta} \mathbb{E}[e^{-\theta X} - 1 + \theta X].$$

D’Souza and Biggins also note that both $r(\theta)$ and $\int_0^{\beta/\alpha} (r(\omega)/\omega) d\omega$ tend to 0 as $\theta \to 0$. Thus for any $\varepsilon > 0$ we can find a $\delta$ such that for all $0 \leq \theta \leq \delta$

$$r(\theta) + \frac{1}{\log c} \int_0^{\beta/\alpha} \frac{r(\omega)}{\omega} d\omega \leq \varepsilon$$

whence $\varphi_n(\theta) \leq e^{-\theta} + \theta \varepsilon$. Take $\varepsilon < 1$, then, noting that $\varphi_n$ is decreasing, we have for all $\theta \geq 0$

$$\varphi_n(\theta) \leq s(\theta) := \begin{cases} e^{-\theta} + \theta \varepsilon & \text{for } 0 \leq \theta \leq -\log \varepsilon \\ \varepsilon - \varepsilon \log \varepsilon & \text{for } -\log \varepsilon \leq \theta < \infty. \end{cases}$$

Observe that $\varepsilon - \varepsilon \log \varepsilon < 1$ for $\varepsilon < 1$, then the result follows on putting $\beta = s(u_0)$. \[ \square \]

Note that Lemma 4 does not require $Z_{0,n}$ to be Böttcher, and will be used again in the next section.

**Proposition 5.** (Exponential upper bound for $\varphi_0$) Suppose that C1–C3 hold, then there exists a $c_1 > 0$ such that for all $0 < \varepsilon < \gamma^-$ we can find a $u_1$ such that for all $u > u_1$

$$\varphi_0(u) \leq \exp\{-c_1 u^{\gamma^-}\}. \tag{7}$$

**Proof:** Let $u_0 = 1/\bar{\mu}$. Define intervals

$$I_0 = [u_0, 1] \quad \text{and}$$

$$I_n = [\mu_{0,n-1}, \mu_{0,n}] \quad \text{for } n > 0.$$

Then for $u \in I_n$ we have $u/\mu_{0,n} \in I_0$, whence from (5) and (6)

$$\varphi_0(u) \leq \varphi_n(u/\mu_{0,n})^a_{0,n}$$

$$\leq \beta^\alpha_{0,n}$$

$$= \exp\{-\log (\beta^{-1})^{\log \alpha_{0,n}/\log \mu_{0,n}}\}$$

$$\leq \exp\{-\log (\beta^{-1})^{u^{\log \alpha_{0,n}/\log \mu_{0,n}}}\}$$

since $\mu_{0,n} \geq u$. Now, given $\varepsilon > 0$, let $N$ be such that for all $n \geq N$

$$\frac{\log \alpha_{0,n}}{\log \mu_{0,n}} \geq \gamma \varepsilon.$$
Then for $u > \mu_{0,N-1} := u_1$ we have $n \geq N$ and so

$$\varphi_0(u) \leq \exp\{-\log (\beta^{-1})u^{\gamma^-}\}.$$

Putting $c_1 = \log (\beta^{-1}) > 0$ gives the result.

Note that if $\gamma^- = \inf_n \log a_{0,n}/\log \mu_{0,n}$, then the result holds with $\epsilon = 0$ and $u_1 = u_0$.

**Proposition 6.** (Exponential upper bound on the law of $W_0$.) Suppose that $C1$–$C3$ hold, then there exists a $c_2 > 0$ such that for all $0 < \epsilon < \gamma^-$ we can find an $x_0$ such that for all $0 \leq x < x_0$

$$P(W_0 < x) \leq \exp\{-c_2x^{\gamma^-}/(1-\gamma^-)\}.$$

**Proof:** Markov's inequality gives

$$P(W_0 < x) = P(e^{-uW_0} > e^{-ux}) \leq e^{ux}\varphi_0(u) \leq \exp\{ux - c_1u^{\gamma^-}\} \text{ from (7)}.$$

(Inequalities of the form $P(W_0 < x) \leq e^{ux}\varphi_0(u)$ are commonly found in the large deviations literature. In particular, an inequality of this sort (proved in the same way) is the starting point of Chernoff's Theorem. See for example Billingsley [6, Section 9].)

Now $ux - c_1u^{\gamma^-}$ has a minimum of

$$-c_2x^{\gamma^-}/(1-\gamma^-)$$

occurring at

$$u = \left(\frac{x}{c_1\gamma^-}\right)^{1/(\gamma^- - 1)}$$

where

$$c_2 = c_1^{1/(1-\gamma^-)} \left(\frac{[\gamma^-]}{[\gamma^-]}^{\gamma^-}/(1-\gamma^-) - [\gamma^-]^{-1/(1-\gamma^-)}\right) > 0.$$

This $u$ is greater than $u_1$ so long as

$$x < x_0 := u_1^{\gamma^- - 1}c_1\gamma^-.$$

Minimising $c_2$ over $0 < \epsilon < \gamma^-$ now gives the result.

Again note that if $\gamma^- = \inf_n \log a_{0,n}/\log \mu_{0,n}$, then the result holds with $\epsilon = 0$ and $x_0 = u_0^{\gamma^- - 1}c_1\gamma^-$.

3.2 Lower bound.

For a lower bound on the law of $W_0$ we again proceed via a bound on $\varphi_0$. A lower bound on $\varphi_0$ is obtained from a rough but uniform lower bound on the $\varphi_n$, which is then refined by suitable application of (5). This clearly will require some additional estimates on $p_{a_{0,n}}^0$, for which we shall need some additional assumptions. Firstly, to guarantee $\gamma^+ < 1$ we need:

C4 $\tilde{p} := \sup \limits_n p_{a_n}^n < 1$.

Secondly, for fixed $m$, say $Z_{m,n}$ has uniform minimum family sizes if there exist some $B, q > 0$ such that

$$p_{a_{m,n}}^m \geq Bq^{a_{m,n}} \text{ for all } n \geq m.$$  

We shall assume

C5 $Z_{0,n}$ has uniform minimum family sizes.

Note that C5 certainly holds if $p := \inf \limits_n p_{a_n}^n > 0$, since in the Böttcher case

$$p_{a_{0,n}}^0 = \prod_{k=0}^{n-1} \left( p_{a_k}^k \right)^{a_{0,k}} \geq \tilde{p} \sum_{k=0}^{n-1} a_{0,k} \geq \tilde{p} a_{0,n},$$

upon noting that $\sum_{k=0}^{n-1} a_{0,k} \leq a_{0,n}$ (by induction, since $a_n \geq 2$). Also, if C5 holds then we can, by adjusting $q$ if necessary, assume $B = 1$.

**Lemma 7.** (Uniform lower bound for all $\varphi_n$.) Suppose C2 and C3 hold, then

$$\varphi_n(u) \geq e^{-u}$$

for all $n$ and $u \geq 0$.

**Proof:** It follows from Theorem 3 that $E W_n = 1$ for all $n$. Thus from Jensen’s inequality

$$\varphi_n(u) = E e^{-u W_n} \geq e^{-u E W_n} = e^{-u}$$

as required.

Note that Lemma 7 does not require $Z_{0,n}$ to be Böttcher, and will be used again in the next section.
PROPOSITION 8. (Exponential lower bound for $\varphi_0$.) Suppose that $C1-C5$ hold, then there exists a $c_1 > 0$ such that for all $0 < \varepsilon < 1 - \gamma^+$ we can find a $u_1$ such that for all $u > u_1$

$$\varphi_0(u) \geq \exp\{-c_1 u \gamma^+\}.$$}

PROOF: From (5) and C5 we have for all $n \geq 0$ (assuming $B = 1$)

$$\varphi_0(u) \geq p_{\alpha_0,n}^{\mu_0,n} \varphi_n(u/\mu_0,n)^{a_0,n}$$
$$\geq (q \varphi_n(u/\mu_0,n))^{a_0,n}$$
$$\geq (q \exp\{-u/\mu_0,n\})^{a_0,n} \text{ from (8)}$$
$$= \exp\{-u/\mu_0,n + \log(1/q)\alpha_0,n\}.$$}

Define intervals

$$I_0 = [1, \bar{u}] \quad \text{and}$$
$$I_n = (\bar{u} \mu_0,n_1, \bar{u} \mu_0,n] \quad \text{for} \quad n > 0.$$

Then for $u \in I_n$ we have

$$\varphi_0(u) \geq \exp\{-\log(1/q) + \bar{u}\alpha_0,n\}$$
$$= \exp\{-\log(1/q) + \bar{u}\log\alpha_0,n/\log\mu_0,n\}$$
$$\geq \exp\{-\log(1/q) + \bar{u}\log\alpha_0,n/\log\mu_0,n\}.$$}

Given $\varepsilon > 0$ let $N$ be such that for all $n \geq N$

$$\frac{\log\alpha_0,n}{\log\mu_0,n} \leq \gamma^+$$

then for all $u > \bar{u} \mu_0,n_1 := u_1$ we get $n \geq N$ and so

$$\varphi_0(u) \geq \exp\{-c_1 u \gamma^+\}$$

where $c_1 = \log(1/q) + \bar{u}$.

Note that if $\gamma^+ = \sup_n \log\alpha_0,n/\log\mu_0,n$, then the result holds with $\varepsilon = 0$ and $u_1 = 1$.

PROPOSITION 9. (Exponential lower bound on the law of $W_0$.) Suppose that $C1-C5$ all hold, then there exists a $c_2 > 0$ such that for all $0 < \varepsilon < 1 - \gamma^+$ we can find an $x_0$ such that for all $0 \leq x < x_0$

$$\mathbb{P}(W_0 < x) \geq \frac{1}{2} \exp\{-c_2 x^{-\gamma^+/(1-\gamma^+)}\}.$$
**PROOF:** Decomposing $\varphi_0$ gives

$$
\varphi_0(u) = E(e^{-uW_0 I(W_0 < x)}) + E(e^{-uW_0 I(W_0 \geq x)}) 
\leq \Pr(W_0 < x) + e^{-ux}(1 - \Pr(W_0 < x))
$$

whence from (9)

$$
P(W_0 < x) \geq \frac{\varphi_0(u) - e^{-ux}}{1 - e^{-ux}} \geq \frac{\exp(-c_1u \gamma^+_1) - \exp(-ux)}{1 - \exp(-ux)} = \exp(-c_1u \gamma^+_1) \frac{1 - \exp(c_1u \gamma^+ - ux)}{1 - \exp(-ux)}.
$$

(10)

Put $u = c_0 x^{1/\gamma^+ (\gamma^+ - 1)}$ for some $c_0$, then $u > u_1$ if and only if $x < (u_1/c_0)^{\gamma^+ - 1} := x_0$. Given this, we have

$$
1 - \exp(c_1u \gamma^+ - ux) = 1 - \exp\left(-\left(c_0 - c_0 \gamma^+_1\right)x \gamma^+ / (\gamma^+ - 1)\right)
$$

and

$$
1 - \exp(-ux) = 1 - \exp\left(-c_0 x \gamma^+ / (\gamma^+ - 1)\right).
$$

Choose $c_0$ so that $c_0 - c_1c_0 \gamma^+_1 = c_0/2$; that is

$$
c_0 = (2c_1)^{1/(1-\gamma^+)}.
$$

Then

$$
\frac{1 - \exp(c_1u \gamma^+ - ux)}{1 - \exp(-ux)} = \frac{1 - \exp\left(-\frac{1}{2}c_0 x \gamma^+ / (\gamma^+ - 1)\right)}{1 - \exp\left(-c_0 x \gamma^+ / (\gamma^+ - 1)\right)} = \frac{1}{1 + \exp\left(-\frac{1}{2}c_0 x \gamma^+ / (\gamma^+ - 1)\right)} \geq \frac{1}{2}.
$$

Plugging this into (10) gives

$$
P(W_0 < x) \geq \frac{1}{2} \exp\left(-c_2 x \gamma^+ / (\gamma^+ - 1)\right)
$$

where $c_2 = \sup_{0 < x < 1-\gamma^+} c_1c_0 \gamma^+_1 < \infty$. □

Again we note that if $\gamma^+ = \sup_n \log a_{0,n}/\log \mu_{0,n}$, then this result holds with $\varepsilon = 0$ and $x_0 = 2c_1$. 
4. SCHRODER CASE

We shall assume throughout this section that $X_n$ is Schröder for all $n$. The varying environment analogues to $\alpha$ are (taking any $m \geq 0$)

$$\alpha^- := \liminf_{n \to \infty} \frac{\log (1/p_{1,m,n}^n)}{\log \mu_{m,n}} \quad \text{and} \quad \alpha^+ := \limsup_{n \to \infty} \frac{\log (1/p_{1,m,n}^n)}{\log \mu_{m,n}}.$$ 

It is easily checked that $\alpha^-$ and $\alpha^+$ are independent of $m$, and that

$$\liminf_{n \to \infty} \frac{\log (1/p_1^n)}{\log \mu_n} \leq \alpha^- \leq \alpha^+ \leq \limsup_{n \to \infty} \frac{\log (1/p_1^n)}{\log \mu_n}.$$ 

Also, note that it is possible to have $\alpha^- < \alpha^+$. We shall write

$$\alpha_+^e \text{ for } \alpha^+ + \varepsilon \quad \text{and} \quad \alpha^-_e \text{ for } \alpha^- - \varepsilon.$$

4.1 UPPER BOUND.

An upper bound on the law of $W_0$ is obtained from an upper bound on $\varphi_0$, just as in the Böttcher case. As before, inequality (5) plays a central role, though some work is required to bring $p_1^{0,n}$ into the picture. This is done using a first term Taylor series approximation of $f_{0,n}$.

We shall need the following additions to our basic assumptions:

$\text{C4} \quad \bar{p} := \sup_n p_1^n < 1.$

$\text{C5A} \quad \underline{p} := \inf_n p_1^n > 0.$

Amongst other things, C4 is used to guarantee $\alpha^- > 0$.

**Lemma 10.** (First term approximation of $f_{m,n}$.) Suppose that C1, C4 and C5A hold. Then for all $t_0 < 1$ and $\varepsilon > 0$ there exists an $N$ such that for all $t \in [0, t_0]$ and $n \geq N + m$

$$f_{m,n}(t) \leq t p_1^{m,n} (1 + \varepsilon)^{(m-n) \log (1/p)}$$

$$\leq t p_1^{m,n} (1 + \varepsilon)^{\log (1/p_1^{m,n})}.$$ 

**Proof:** We note to begin with that

$$f_{m,n}(t) \xrightarrow{n \to \infty} 0 \text{ uniformly in } m \text{ and } t \in [0, t_0]$$

since (from C4)

$$f_n(t) \leq \bar{p} t + (1 - \bar{p}) t^2 := g(t)$$
and thus
\[ f_{m,n}(t) \leq g^{(n-m)}(t) \xrightarrow{n \to \infty} 0 \text{ uniformly on } [0, t_0] \]
where \( g^{(k)} \) is the \( k \)-fold composition of \( g \). Also

\[(13) \quad f'_{n}(t) \xrightarrow{t \downarrow 0} p_1^n \text{ uniformly in } n \]
since (from C1)

\[ |f'_{n}(t) - p_1^n| = 2p_2^n t + 3p_3^n t^2 + \cdots \leq \mu_n t \leq \bar{\mu} t. \]

Now, as \( f_{m,n}(0) = 0 \), (11) will follow if we can establish that

\[ f'_{m,n}(t) \leq p_1^{m,n}(1 + \varepsilon)^{(n-m)\log(1/p)}. \]

Taking logarithms, this is equivalent to requiring

\[ \frac{1}{n-m} \log \frac{f'_{m,n}(t)}{p_1^{m,n}} \leq \log (1 + \varepsilon) \log (1/p) =: \varepsilon'. \]

which in turn is equivalent to

\[ \frac{1}{n-m} \sum_{k=m}^{n-1} \log \frac{f'_{k}(f_{k+1,n}(t))}{p_1^k} \leq \varepsilon'. \]

For \( \delta > 0 \) let \( t_1 \) be such that for \( 0 \leq t \leq t_1 \), \( f'_{n}(t) \leq p_1^n + \delta \), and let \( K \) be such that for all \( t \in [0, t_0] \) and \( n - m \geq K \), \( f_{m,n}(t) \leq t_1 \). That \( t_1 \) and \( K \) exist follows from (13) and (12) respectively. We have

\[ \frac{1}{n-m} \sum_{k=m}^{n-1} \log \frac{f'_{k}(f_{k+1,n}(t))}{p_1^k} \leq \frac{1}{n-m} \sum_{k=m}^{n-1-K} \log \frac{p_1^k + \delta}{p_1^k} + \frac{1}{n-m} \sum_{k=n-K}^{n-1} \log \frac{\bar{\mu}}{p} \]

\[ \leq \frac{\delta}{p} + \frac{K}{n-m} \log \frac{\bar{\mu}}{p} \quad \text{(from C5A)}. \]

Choose \( \delta \) so that \( \delta/p \leq \varepsilon'/2 \) and \( N \) such that \( (K/N) \log \bar{\mu}/p \leq \varepsilon'/2 \), then the result follows.
PROPOSITION 11. (Algebraic upper bound for \( \varphi_0 \).) Suppose that C1–C4 and C5A hold, then for all \( 0 < \varepsilon < \alpha^- \) we can find a \( u_1 \) such that for all \( u > u_1 \)

\[
\varphi_0(u) \leq u^{-\alpha^-}.
\]

PROOF: For some (arbitrary) \( u_0 > 0 \) we define intervals

\[
I_n = [u_0 \mu_0,n, u_0 \mu_0,n+1) \quad \text{for all} \quad n \geq 0.
\]

Using this \( u_0 \) in Lemma 4 gives for \( u \in I_n \), \( \varphi_n(u/u_0,n) \leq \beta < 1 \). Let \( t_0 = \beta \), then from Lemma 10 we have an \( N_1 = N_1(\varepsilon) \) such that for \( n \geq N_1 \) (that is, for \( u > u_0 \mu_0,N_1 \))

\[
\varphi_0(u) = \varphi_0(u_0,n(u/u_0,n))
\]

\[
\leq f_0,n(\beta)
\]

\[
\leq \beta p_1^{0,n}(1 + \varepsilon) \log \left( \frac{1}{p_1^{0,n}} \right)
\]

\[
= \beta \mu_0,n
\]

\[
\leq \beta (u/u_0 \mu)^{-1} \log \left( \frac{1}{p_1^{0,n}} \right) / \log \mu_0,n.
\]

Let \( N_2 = N_2(\varepsilon) \) be such that for \( n \geq N_2 \)

\[
\log \left( \frac{1}{p_1^{0,n}} \right) / \log \mu_0,n \geq \alpha^-,
\]

then for all \( u > u_0 \max \{ \mu_0,N_1, \mu_0,N_2 \} := u_1 \) we have

\[
\varphi_0(u) \leq \beta (u/u_0 \mu)^{-(1 - \log (1 + \varepsilon)) \alpha^-} \leq \beta (u/u_0 \mu)^{-\alpha^-},
\]

where \( \varepsilon_* \downarrow 0 \) as \( \varepsilon \downarrow 0 \). Finally, choose \( u_0 \) to give \( \beta (u_0 \mu)^{\alpha^-} = 1 \) and the result follows.

PROPOSITION 12. (Algebraic upper bound on the law of \( W_0 \).) Suppose that C1–C4 and C5A hold, then there exists a \( c_1 > 0 \) such that for all \( 0 < \varepsilon < \alpha^- \) we can find an \( x_0 \) such that for all \( 0 \leq x < x_0 \)

\[
P(W_0 < x) \leq c_1 x^\alpha^-.
\]

PROOF: As in the proof of Proposition 6, we get from (14) that

\[
P(W_0 < x) \leq e^{ux} \varphi_0(u) \leq e^{ux} u^{-\alpha^-}.
\]

Minimising with respect to \( u \) gives at \( u = \alpha^- x^{-1} \)

\[
P(W_0 < x) \leq \left( \frac{e}{\alpha^-} \right)^{\alpha^-} x^{\alpha^-} \leq c_1 x^{\alpha^-}
\]

where \( c_1 = \sup_{0 < \varepsilon < \alpha^-} \left( \frac{e}{\alpha^-} \right)^{\alpha^-} < \infty \). Putting \( x_0 = \alpha^- u_1^{-1} \) gives the result.
4.2 Lower Bound.

The lower bound is found quite easily in the Schröder case.

**Proposition 13.** (Algebraic lower bound for $\varphi_0$.) Suppose that C1–C3 hold, then there exists a $c_1 > 0$ such that for all $0 < \varepsilon < \varepsilon_0$ ($\varepsilon_0 < \infty$ given) we can find a $u_1$ such that for all $u > u_1$

\begin{equation}
\varphi_0(u) \geq c_1 u^{-\alpha^+_e}.
\end{equation}

**Proof:** From (5) and (8) we have

\[ \varphi_0(u) \geq p_1^{0,n} \varphi_n(u/\mu_0,n) \geq p_1^{0,n} e^{-u/\mu_0,n}. \]

Let

\[ I_0 = [1/\mu, 1] \quad \text{and} \quad I_n = (\mu_{0,n-1}, \mu_{0,n}] \quad \text{for} \quad n > 0 \]

then for $u \in I_n$ we have

\[ \varphi_0(u) \geq p_1^{0,n} e^{-1} = \frac{-\log (1/p_1^{0,n})}{\log \mu_{0,n}} e^{-1} \geq (u/\mu)^{-\log (1/p_1^{0,n})/\log \mu_{0,n} e^{-1}}. \]

Given $\varepsilon > 0$, let $N$ be such that for all $n \geq N$

\[ \frac{\log (1/p_1^{0,n})}{\log \mu_{0,n}} \leq \alpha^+_e \]

then for $u > \mu_{0,N-1} := u_1$, we have $n \geq N$ and so

\[ \varphi_0(u) \geq c_1 u^{-\alpha^+_e} \]

where $c_1 = \mu^{-\alpha^+_e} e^{-1} > 0$.

Note that if $\alpha^+_e = \sup_{n} \log (1/p_1^{0,n})/\log \mu_{0,n}$, then the result holds with $\varepsilon = 0$ and $u_1 = 1/\mu$. 

\[ \square \]
PROPOSITION 14. (Algebraic lower bound on the law of \( W_0 \).) Suppose that C1–C3 hold, then for all \( 0 < \epsilon < \epsilon_0 \) (\( \epsilon_0 \) given) there exists a \( c_2 > 0 \) and an \( x_0 \) such that for all \( 0 \leq x < x_0 \)

\[
P(W_0 < x) \geq c_2 x^{\alpha^+_\epsilon}.
\]

PROOF: Just as in the proof of Proposition 9, we can decompose \( \varphi_0 \) to give

\[
P(W_0 < x) \geq \frac{\varphi_0(u) - e^{-ux}}{1 - e^{-ux}}
\]

\[
\geq c_1 u^{-\alpha^+_\epsilon} - e^{-ux} \quad \text{from (15)}.
\]

Put

\[
u = \frac{\alpha^+_\epsilon}{2\epsilon} x^{-1} \log x^{-1}
\]

then \( u > u_1 \) provided \( x/\log(1/x) < \alpha^+/u_1 \). For such \( x \) we get

\[
P(W_0 < x) \geq c_1 x^{\alpha^+_\epsilon} \left( \alpha^+_\epsilon \log x^{-1} \right)^{-\alpha^+_\epsilon - x^{\alpha^+_\epsilon}}
\]

\[
= x^{\alpha^+_\epsilon} \left[ c_1 x^{-\epsilon} \left( \alpha^+_\epsilon \log x^{-1} \right)^{-\alpha^+_\epsilon} - 1 \right].
\]

Now \( \left[ c_1 x^{-\epsilon} \left( \alpha^+_\epsilon \log x^{-1} \right)^{-\alpha^+_\epsilon} - 1 \right] \uparrow \infty \) as \( x \downarrow 0 \). Thus for any \( \epsilon > 0 \) we can choose an \( x_0 \) such that \( x < x_0 \) implies \( x/\log(1/x) < \alpha^+/u_1 \) and

\[
0 < c_2 := \inf_{x \in [0, x_0]} \left[ c_1 x^{-\epsilon} \left( \alpha^+_\epsilon \log x^{-1} \right)^{-\alpha^+_\epsilon} - 1 \right]
\]

whence the result. \( \square \)

5. MIXED CASE

Some results are still possible when \( Z_{0,n} \) is neither Schröder nor Böttcher. For the purposes of this section we shall assume that \( X_{n_k} \) is Böttcher for all \( k \), where \( n_k \uparrow \infty \) as \( k \uparrow \infty \), and that all the other \( X_n \) are either Böttcher or Schröder.

Before proceeding we shall need some more notation. Let \( \tilde{f}_k = f_{n_k, n_{k+1}} \) and let \( \tilde{X}_k \) be a random variable with this probability generating function, that is \( \tilde{X}_k \overset{D}{=} Z_{n_k, n_{k+1}} \). Write \( \tilde{\mu}_k \) for \( \mathbb{E} \tilde{X}_k \), then we have the following weakenings of our basic assumptions:

\( \tilde{C}1 \) \( \tilde{\mu} := \sup_k \tilde{\mu}_k < \infty \).

\( \tilde{C}2 \) \( \tilde{Z}_{0,k} := Z_{n_0, n_k} \) is uniformly supercritical.

\( \tilde{C}3 \) All the \( \tilde{X}_k/\tilde{\mu}_k \) are dominated by some \( \tilde{X} \) with \( \mathbb{E} \tilde{X} \log^+ \tilde{X} < \infty \).
Clearly $\tilde{X}_k$ is Böttcher for all $k \geq 0$, so we can apply our previous results for the Böttcher case directly to the current situation. Let

$$\gamma^- = \liminf_{k \to \infty} \frac{\log a_{n_0,n_k}}{\log \mu_{n_0,n_k}} \quad \text{and} \quad \gamma^+ = \limsup_{k \to \infty} \frac{\log a_{n_0,n_k}}{\log \mu_{n_0,n_k}}$$

and put

$$\gamma^+_\varepsilon = \gamma^+ + \varepsilon \quad \text{and} \quad \gamma^-_\varepsilon = \gamma^- - \varepsilon.$$

As before, $\tilde{C}1$ is sufficient to guarantee $\gamma^- > 0$.

**Proposition 15.** (Upper bound in the mixed case.) Suppose that $\tilde{C}1-\tilde{C}3$ hold, then there exists a $c_1 > 0$ such that for all $0 < \varepsilon < \gamma^-$ we can find an $x_0$ such that for all $0 \leq x < x_0$

$$P(W_{n_0} < x) \leq \exp\{-c_1 x^{-\gamma^-_\varepsilon} / (1 - \gamma^-_\varepsilon)\}.$$ 

Moreover if $\gamma^- = \inf_k \log a_{n_0,n_k} / \log \mu_{n_0,n_k}$ then the result holds with $\varepsilon = 0$.

For the lower bound we shall need the following additional assumptions:

$\tilde{C}4$ \hspace{1cm} $\tilde{p} := \sup_k p^{n_k,n_{k+1}}_{n_k,n_k} < 1$, which guarantees $\gamma^+ < 1$, and

$\tilde{C}5$ \hspace{1cm} $\tilde{Z}_{0,k}$ has uniform minimum family sizes.

**Proposition 16.** (Lower bound in the mixed case.) Suppose that $\tilde{C}1-\tilde{C}5$ hold, then there exists a $c_2 > 0$ such that for all $0 < \varepsilon < 1 - \gamma^+$ we can find an $x_0$ such that for all $0 \leq x < x_0$

$$P(W_{n_0} < x) \geq \frac{1}{2} \exp\{-c_2 x^{-\gamma^+_\varepsilon} / (1 - \gamma^+_\varepsilon)\}.$$ 

Moreover if $\gamma^+ = \sup_k \log a_{n_0,n_k} / \log \mu_{n_0,n_k}$ then the result holds with $\varepsilon = 0$.

Finally, note that it follows immediately from Propositions 15 and 16 that if $\tilde{C}1-\tilde{C}3$ hold then

$$\liminf_{z \to 0} \frac{\log \log P(W_{n_0} < x)}{-\log x} \geq \frac{\gamma^-}{1 - \gamma^-}$$

and if $\tilde{C}4$ and $\tilde{C}5$ also hold then

$$\limsup_{z \to 0} \frac{\log \log P(W_{n_0} < x)}{-\log x} \leq \frac{\gamma^+}{1 - \gamma^+}.$$

Clearly, analogous inequalities can be derived from Propositions 6, 9, 12 and 14.
