The *xyn2* gene of a filamentous mesophilic fungus, *Trichoderma reesei*, coding xylanase 2 (*Xyn2*) was previously expressed in *Pichia pastoris*. In the present study, the recombinant Xyn2 was prepared from a 15 litre fermenter, and subsequently characterised. It has been confirmed to have a molecular mass of 21 kDa, an optimal pH of 6·0 and an optimal temperature of 60°C. When tested using oat-spelt xylan, it showed a *K_m* and catalytic rate constant (*k_cat*) of 1·1 mg/ml and 512·4/s, respectively. Analysis of the products from oat-spelt xylan degradation confirmed that the enzyme was an endo-xylanase with xylotriose and xylobiose as the main degradation products. The unprocessed Xyn2 was supplemented to a xylan-containing diet to determine its influences on performance and nutrient digestibilities by weaned pigs. Results showed that the average body-weight gain increased 16·9 % when piglets received Xyn2 at a concentration of 500 U/kg diet. There also was a positive effect (0·05 < *P*<0·10) on the digestibility values of crude protein, ash, Ca and acid-detergent fibre with Xyn2 supplementation. The potential benefits of Xyn2 in the nutrition of weaned pigs should make it an alternative applicant for industrial xylanase production.

Xylanase: Characterisation: Weaned pigs: Supplementation: Digestibility

Xylan, the major component of hemicellulose, is a heterogeneous polysaccharide with a backbone consisting of a β-D-(1 → 4)-linked xylopyranoside backbone substituted with many side chains. Complete breakdown of xylans requires the synergistic action of several enzymes of which endo-β-1,4-xylanases (EC 3.2.1.8) are the crucial enzymes for depolymerisation. In recent years, xylanases have attracted considerable research interest because of their potential benefits in the animal nutrition and feed industry. The cell walls of cereals contain up to 15 % NSP; exogenous enzymes can hydrolyse these carbohydrates into smaller units that can be utilised by animals.

The fungus *Trichoderma reesei* is a filamentous mesophilic fungus which has been shown to secrete large amounts of efficient xylan-degrading enzymes. The *T. reesei* xylanase 2 (*Xyn2*) has been in industrial use for many years, since it represents more than 50 % of the total xylanolytic activity of this fungus. However, the industrial enzymes are often used in the unpurified form. There are many side activities that can be a problem with the use of these enzymes. For instance, the relatively crude xylanase preparation with residual cellulolytic activity requires the careful control of process parameters to avoid damage to fibres. In addition, the residual protease may degrade xylanases of interest over time. The *T. reesei* Xyn2 produced in a recombinant host has an advantage of showing xylanase activity that is practically free of harmful side activities. Therefore, the recombinant production hosts are preferred. We have previously expressed the *xyn2* gene in *Pichia pastoris* and achieved a high expression level of 500 U/ml in a 5 litre fermenter. To evaluate its potential benefits for industrial applications, especially in the animal nutrition and feed industry, the enzyme has been studied to understand its physical and biochemical characteristics. Furthermore, a trial with weaned pigs has been carried out to validate the potential benefits under practical conditions.

Materials and methods

Micro-organisms and media

Recombinant *P. pastoris* (PX-1) was previously constructed and conserved in our laboratory. PX-1 was cultivated on either buffered glycerol–complex medium (1 % yeast extract, 2 % peptone, 1·34 % yeast nitrogen base, 1 % glycerol) or buffered methanol–complex medium (1 % yeast extract, 2 % peptone, 1·34 % yeast nitrogen base, 1 % methanol), respectively. Zeocin was added to a final concentration of 100 μg/ml.

Xylanase 2 production in a 15 litre fermenter

A large-scale production was performed (six times) in a 15 litre fermenter (Nanjing Runze Bioengineering Equipment Co., Ltd, Nanjing, China). Xylanase 2 production in a 15 litre fermenter

A large-scale production was performed (six times) in a 15 litre fermenter (Nanjing Runze Bioengineering Equipment Co., Ltd, Nanjing, China). The residual protease may degrade xylanases of interest over time. The *T. reesei* Xyn2 produced in a recombinant host has an advantage of showing xylanase activity that is practically free of harmful side activities. Therefore, the recombinant production hosts are preferred. We have previously expressed the *xyn2* gene in *Pichia pastoris* and achieved a high expression level of 500 U/ml in a 5 litre fermenter (He Jun, Yu Bing, Zhang Keying and Chen Daiwen, unpublished results). To evaluate its potential benefits for industrial applications, especially in the animal nutrition and feed industry, the enzyme has been studied to understand its physical and biochemical characteristics. Furthermore, a trial with weaned pigs has been carried out to validate the potential benefits under practical conditions.
Co. Ltd, Nanjing, China). PX-1 was cultured in 2 litre Erlenmeyer flasks containing 500 ml of buffered glycerol–
complex medium at 30°C on a rotary shaker at 200 rpm. After 18–20 h incubation, cell pellets were harvested by
centrification at 3000 g for 5 min. For xylanase induction,
the cell pellets were re-suspended in 9 litres of buffered
methanol–complex medium. The induction was maintained
for 5 d by adding absolute methanol to a final concentration of
1 % every day. Relative percentage of dissolved oxygen was
maintained above 30 % via adjusting the agitation rate.
Supernatant fraction samples were collected every day and
kept at –8°C before analysis. At the end of fermentation,
all culture supernatant fraction was collected by centrifri-
gation and subsequently used as the enzyme source for the
animal trial.

SDS-PAGE and enzyme activity assay
SDS-PAGE on 15 % polyacrylamide was performed by the
method of Laemmli(9). The protein fractions (induction
supernatant fraction) were boiled for 3 min and applied to
the gel. Proteins were visualised by Coomassie brilliant blue
R 250 staining. The protein concentration was determined
by the Bradford assay using bovine serum albumin as a
standard(10). Xylanase activity was assayed by the method
described by Bailey et al.(11), with 1 % oat-spelt xylan
(Sigma, St Louis, MO, USA) as the substrate at 50°C
for 10 min. Appropriate dilutions of the recombinant protein
(culture supernatant fraction) in 50 mM-sodium citrate buffer
(pH 5.0) were used as the enzyme source. The amount of
released sugar was determined by the dinitrosalicylic acid
method described by Miller(12). One unit of xylanase
activity was defined as the quantity of enzyme that liberated
reducing sugar at the rate of 1 μmol/s. The temperature
optimum was measured by performing the xylanase activity
assay at temperatures ranging from 20 to 90°C. Thermostat-
ability was tested by heating the enzyme samples for different
times at various temperatures, and the activity was assayed at
50°C for 10 min. Assays at different pH values were
performed at the optimal temperature over a pH range of 3.0
to 8.0. The buffers used were 50 mM-citrate (pH 3.0),
50 mM-citrate phosphate (pH 4.0 to 7.0) and 50 mM-phosphate
(pH 8.0), respectively.

Analysis of substrate specificity and hydrolysis products
The substrates (birchwood xylan, oat-spelt xylan, beechwood
xylan, gellan gum and carboxymethyl cellulose) were
purchased from Sigma Chemical Co. (St Louis, MO, USA).
Avicel (cellulose microcrystalline) was purchased from
Merck (Darmstadt, Germany). The determining of substrate
specificity was carried out in 50 mM-citrate phosphate (pH
5.0) containing 2.0 mg/ml of each substrate at 50°C for
10 min. For each assay, six different substrate concentra-
tions were prepared in 50 mM-citrate phosphate (pH 5.0),
and incubated with the enzyme at 50°C for 5 min. The \( K_m \)
and catalytic rate constant \( k_{cat} \) values were calculated from
the kinetics data as described by Jiang et al. (8).

Oat-spelt xylan (40 mg) was incubated with 100 U of the
enzyme in 2 ml 50 mM-citrate phosphate (pH 5.0) and
the reaction was performed at 50°C for 12 h. The hydrolysis
products were analysed by TLC using silica gel plates 60F
254 (E. Merck, Darmstadt, Germany). Aliquots (100 μl) of
the samples were collected at 5, 10 and 30 min, and at 1, 2,
4, 8 and 12 h of the incubation period and 1 μl of the sample was spotted on the TLC plates. The plates were
subsequently developed with two runs of acetonitrile–water
(85:15, v/v) followed by heating for a few minutes at 130°C
in an oven after spraying the plates with a methanol–sulfuric
acid mixture (95.5, v/v)8. A xylo-oligosaccharide mixture
(Suntory Ltd, Osaka, Japan) consisting of xylose, xylobiose
and xylotriose was used as the standard.

Animals and housing
The experimental protocols used in the present study were
approved by Sichuan Agricultural University Institutional
Animal Care and Use Committee. Twenty-four weaned pigs
(Duroc × Landrace × Yorkshire) with an average initial body
weight of 10.2 ± 0.35 kg were selected and randomly allotted
to four dietary treatments (n 6) with equal numbers of
males and females in each group. Treatments consisted of:
(1) control without Xyn2 supplementation; (2) Xyn2 added
at a concentration of 500 U/kg diet (LD); (3) Xyn2 added at
a concentration of 1000 U/kg diet (MD); (4) Xyn2 added at
a concentration of 1500 U/kg diet (HD).

Pigs were housed individually in metabolism cages
(0.7×1.5 m) with woven wire flooring in an environmentally
controlled room (22–24°C) and were given ad libitum access
to water through a water nipple. Pigs were hand-fed four times
per d (08.00, 12.00, 16.00 and 20.00 hours) in bowl feeders to
make sure fresh feed was available, and allowed a 5 d
adjustment to the experimental diets. The diet adjustment
period was followed by a collection period, which include a
4 d collection of faeces to determine the apparent nutrient
digestibility. Pig weights and feed consumption were
determined daily throughout the duration of the trial.

Experimental diets
To prepare a diet containing sufficient amounts of the target
substrate (xylan), both wheat and wheat bran were utilised.
The diet was formulated on the basis of nutrient requirements
for 10–20 kg pigs (National Research Council(13)). Dietary
amino acids were supplied by maize, wheat, soyabean meal,
rapeseed meal, fish meal, and vitamin and minerals were
supplied by vitamin and mineral supplements (Table 1). Synthetic DL-methionine was added to the diets to meet
minimal methionine–cystine concentrations. Each ingredient
source was analysed for protein and amino acid content.
The analysed amino acid contents of the ingredients were
used to formulate the experimental diets. The unprocessed
enzyme (obtained from fermentation) was added to the diet
by using a portion of the basal diet (5.0 kg/100 kg of entire
diet) as the carrier.

Sample collection and analysis
Faeces were collected and weighed every 24 h, with 5 %
samples being saved and blended for each pig within the
collection period. Then the total quantity of faeces collected
was pooled and freeze-dried to a constant weight. The dried
faecal matter was ground and stored at 4°C until it was analysed for nutrients.

Quantitative composition was determined on each of the samples using the following analytical methods: DM content according to AOAC method 964·22; crude protein according to method 955·04; ash according to method 923·03; Ca according to method 927·02; P according to method 965·05 (14). The acid-detergent fibre content was determined following the procedures of Van Soest et al. (15). Gross energy was determined using an adiabatic oxygen bomb calorimeter (Parr Instrument Co., Moline, IL, USA).

Calculation and statistical analysis

The experimental model used was a completely randomised design with four treatments of added enzyme. Data from the animal trial were analysed with an ANOVA procedure of SPSS 13.0 (SPSS Inc., Chicago, IL, USA) followed by Duncan’s test for multi-group comparisons. To determine whether there was a significant linear response to the enzyme, the orthogonal polynomial contrasts were carried out using the general linear model (GLM) procedure. Data were expressed as mean values with their standard errors. Differences with $P < 0.05$ were considered to be significant.

Results

Xylanase 2 production in a 15 litre fermenter

The recombinant $P$. pastoris PX-1 was cultured in a 15 litre fermenter. To determine the highest xylanase yield, the experiment was repeated three times. The size of recombinant xylanase (Xyn2) determined by SDS-PAGE was 21 kDa, similar to that of the native xylanase secreted by $T$. reesei (Fig. 1). Xyn2 was the major protein (over 90 % of total protein as detected by densitometry) secreted by PX-1 into the culture medium. Therefore, the procedure for protein purification was not necessary. The highest xylanase activity (560 U/ml) in the culture supernatant fraction was recorded after 78 h induction (Fig. 2). However, the highest cell wet weight (78 g/l) was obtained at 96 h. Both xylanase activity and cell wet weight decreased slightly in the late induction period (after 96 h).

Effect of pH and temperature on β-xylanase activity

The recombinant β-xylanase activity peaked between pH 4·5 and 7·5, with the highest activity measured at pH 6·0 in 50 mM-citrate buffer (Fig. 3(A)). The optimal temperature

Fig. 1. SDS-PAGE analysis for products in the culture supernatant fraction. M, protein marker; 1–6, culture supernatant fraction after 60, 66, 72, 78, 84 and 90 h fermentation.

Fig. 2. Enzyme production of $P$. pastoris (PX-1) and cell wet weight after induction at different times. (–•–), Xylanase activity; (–△–), cell wet weight. Values are means, with standard errors represented by vertical bars.
for this enzyme was at 60°C (Fig. 3(B)). Although the highest activity was measured at 60°C, the enzyme was not stable at this temperature (only 30% activity retained after 30 min incubation at 60°C). However, the enzyme was stable at 50°C, and the total activity remained more than 94% after 30 min incubating at this temperature (Fig. 3(C) and (D)).

Analysis of substrate specificity and hydrolysis products

The hydrolytic activity of the recombinant enzyme on various substrates was determined (Table 2). The highest activity (100%) was observed with the oat-spelt xylan followed by the birchwood xylan (91%). The enzyme exhibited relatively low activities towards cellulosic substrates, such as gellan gum (12%), Avicel (1-7 %) and carboxymethyl cellulose (1-5%). The Michaelis–Menten constants were determined for the substrates. The $K_m$ and catalytic rate constant ($k_{cat}$) were 1-8 mg/ml and 435-7/s for birchwood xylan, and 1-1 mg/ml and 512-4/s for oat-spelt xylan, respectively. The predominant endproducts of hydrolysis of oat-spelt xylan were xylobiose and xylotriose (Fig. 4). The results confirmed that the recombinant Xyn2 was an endoxylanase.

Effect of xylanase 2 on performance of weaned pigs

As shown in Fig. 5, there was a positive effect of enzyme treatment (500 U/kg) on average daily body-weight gain.

Discussion

In recent years, several commercial enzymes have been produced to act on carbohydrates not readily digested by single-stomached animals. These are known as NSP and have anti-nutritional properties, depressing animal performance. NSP of particular concern include β-glucans, xylans, pentosans and arabinogalactans. Today, the two extensively used enzymes are xylanase in wheat-based diets and β-glucanase in barley-based diets. Enzyme supplementation to diets for poultry has usually shown more beneficial effects than supplementation to diets for pigs, particularly if highly viscous diets are used. The mechanisms of xylanase action can be attributed to the reduced water-holding capacity and subsequent gut fill, and increased digestibility of the cell wall fraction, and a decrease in gut viscosity, resulting in a greater exposure of the gut contents to absorptive surfaces.

Currently, heterologous expression has become one of the main tools for the production of industrial enzymes. Many xylanase genes have been successfully expressed in different hosts. In our laboratory, the xyn2 gene of T. reesei, coding Xyn2, was previously expressed in P. pastoris. The complete characterisation of the recombinant enzyme (Xyn2) is a key-point condition to evaluate the possibility of its use in industrial applications. As shown in the present study, the recombinant Xyn2 is the predominant protein in the extracellular medium (Fig. 1). The molecular mass (21 kDa) is close to previously purified T. reesei Xyn2. The highest β-xylanase activity (560 U/ml) for PX-1 was obtained in a 15 litre fermenter after 78 h fermentation (Fig. 2). The expression level is higher than that of levels obtained from a recombinant Saccharomyces cerevisiae strain (90 U/ml) or any Escherichia coli expression system. The expression level compares well with that of hyperproducing mutant T. reesei VTT-D-86271 (324 U/ml) if one takes into account that the T. reesei culture supernatant fraction contains the complete battery of enzymes involved in xylan degradation. The pH and temperature optima (pH 6.0; 60°C) of the recombinant Xyn2 compares well with Xyn2 secreted by recombinant S. cerevisiae. Both of them have a moderate thermostability and inactivated rapidly above 60°C. The hydrolytic activity of the recombinant Xyn2 on various substrates was determined in the present study (Table 2). The highest activity (100%) was observed with the oat-spelt xylan as the substrate followed by the birchwood xylan (91%). The Km for oat-spelt xylan and birchwood xylan was 1.1 and 1.8 mg/ml, respectively. The higher affinity towards oat-spelt xylan indicated that the recombinant Xyn2 is more suitable for use in the feed industry other than the paper industry. The products of hydrolysis of oat-spelt xylan were predominantly xylotriose and xylobiose.

Fig. 4. Analysis of the hydrolysed products by recombinant xylanase 2. Oat-spelt xylan (40 mg) was incubated with 100 U of the enzyme in 2 ml 50 mM-citrate phosphate (pH 5.0) and the reaction was performed at 50°C for 12 h and then the hydrolysates were analysed by TLC. M, protein marker.

Fig. 5. Effect of recombinant xylanase 2 (Xyn2) supplementation on average daily body-weight gain (ADG) in weaned pigs (n=6). Values are means, with standard errors represented by vertical bars. Mean values with unlike letters were significantly different (P<0.05).
and a smaller amount of xylose (Fig. 4), which confirmed the endo-acting nature of the recombinant Xyn2. The xylo-oligosaccharides (i.e. xylobiose) have been found to have a stimulatory effect on the selective growth of intestinal bifidobacteria, which are important for the maintenance of a healthy intestinal microflora(23).

In the present study, the potential benefits of the recombinant enzyme in the nutrition of weaned pigs have been validated. Previous study has shown that pigs receiving enzyme-supplemented diets usually fail to show the same consistent improvements in nutrient digestibilities and growth performance as observed in poultry(24). However, in young pigs, poor nutrient utilisation has been attributed, in part, to the immaturity of the digestive system, including hydrolysis of NSP. Significant improvements in growth performance and nutrient digestibilities were observed when xylanase was supplemented to wheat-based diets(3). In the present study, our statistics results showed a significant linear response to the recombinant Xyn2. The supplementation of recombinant Xyn2 (500 U/kg diet) increased the apparent digestibilities of crude protein, ash, Ca and acid-detergent fibre, which is consistent with an improved performance (average body-weight gain) and feed efficiency (Fig. 5). Yin et al. (25) also reported increases in the digestibilities of some nutrients when xylanase was supplemented to a wheat-based diet in studies with grower pigs. It has to be mentioned that xylanase supplementation may not be effective if sufficient amounts of the target substrate are unavailable. In the present study, the entire diet contained xylans at a level of 5.76%.

Despite the positive effect of enzyme supplementation on performance and nutrient digestibilities in the LD group, there was no improvement of such parameters in the MD and HD groups. This might be explained, in part, by the liquid form of the enzyme. The enzyme prepared through fermentation usually has a bad odour. The bad odour together with a greater enzyme supplementation in the diet may decrease the feed intake. This was supported by the present results, as the feed intake decreased 6.7% in the MD group and 5.1% in the HD group, respectively (Fig. 6(A)). Therefore, a proper process step, such as ultrafiltration, dilution and spray drying is indispensable to the fermentative products(26,27).

In conclusion, the results obtained from the present study indicated that the recombinant Xyn2 is more suitable for use in the feed industry. A diet supplemented with the unprocessed enzyme at a lower level improves both the performance and nutrient digestibilities in weaned pigs. However, a proper process is needed to improve its potential benefits in the nutrition of young pigs.

**Table 3.** Influence of recombinant xylanase 2 (Xyn2) supplementation on nutrient digestibilities of weaned pigs (n = 6) (Mean values with their standard errors)

Control, without Xyn2 supplementation; LD, Xyn2 added at a concentration of 500 U/kg diet; MD, Xyn2 added at a concentration of 1000 U/kg diet; HD, Xyn2 added at a concentration of 1500 U/kg diet.

<sup>a,b</sup><sup>c</sup> Mean values within a row with unlike superscript letters were marginally significantly different (P < 0.10).

![Fig. 6.](image-url) Effect of recombinant xylanase 2 (Xyn2) supplementation on feed intake (A) and feed efficiency (B) in weaned pigs (n = 6). Values are means, with standard errors represented by vertical bars. *<sup>a</sup><sup,b</sup> Mean values with unlike letters were significantly different (P < 0.05).
Acknowledgements

The present study was funded by the Feed Biotechnology Project of Sichuan Province of China with grant no. 2007Z06-050, the YouthFund Project of Sichuan Ministry of Education with grant no. 00924200 and the Program for Changjiang Scholars and Innovative Research Team in University with grant no. IRT055-5, China Ministry of Education.

J. H., J. Y. and L. W. participated in the experimental design, carried out the molecular genetic and biochemical experiments, participated in data interpretation and helped draft the manuscript. B. Y. conceived of the study. D. C. directly supervised the project, participated in its experimental design and data interpretation and was responsible for writing the manuscript.

The authors state that there are no conflicts of interest in this field.
