Introduction: To present the result of a 5 year follow up study in a pediatric population (www.innoforce.ch)

Methods: Our study was included 50 ears which had a cholesteatoma surgery with a recent CT which was performed at least 5 years subsequent to the first surgery. Middle ear aeration was graded using the following scale: 0, no aeration in the middle ear; 1, only the mesotympanum is aerated; 2, the entire tympanic cavity, including the attic, is aerated; and 3, the tympanic and mastoid cavities are aerated. The staged CWUT with mastoid cortex plasty was selected for 23 ears with grade 3 aeration (well-aerated ears group). Results: Aeration between 1stSOP and 2ndSOP was improved in 70% of all. By bony mastoid obliteration, 69% of grade 2 ears and 90% of grade 1 ears maintained their aerations. A deep pocket formation occurred in 0% of grade 3 and 2 ears, 20% of grade 1 ears and 33% of grade 0 ears. There was no significant group difference in aeration level during 1stSOP, and the proportion of the two groups during 2ndSOP was 48% vs. 47%.

Conclusions: Staging is instructive for understanding long-term changes in aeration status. The selection of mastoid cortex plasty or bony mastoid obliteration is suitable and reliable for stabilizing postoperative aeration levels.

Learning Objectives:

Introduction: If poor postoperative aeration can be accurately predicted, canal wall down tympanoplasty or obliteration technique is preferable to canal wall up tympanoplasty (CWUT) is described, however, little is known about the dynamics of middle ear aeration. We sought to determine how the aeration levels changed during the first- and second-stage operations (1stSOP and 2ndSOP), and the most recent CT examinations (recent CT).

Methods: Our study was included 50 ears which had a cholesteatoma extending into the antrum or mastoid cavity involving the ossicular chain with varying degrees of scutum defect.

Red Cross hospital affiliated to xi’an jiaotong university

Learning Objectives: Otitis media is the most common otology diseases, with the development of imaging and ear microsurgery, the close type - keep plane wall of mastoid tympanic cavity forming or open - removal of the external auditory canal mastoid lesions cleared a parallel tympanic cavity forming period tympanoplasty, eventually reach function reconstruction, restore hearing. We have between January 2011 and January 2011, 120 cases of surgical observation data integrity is comming back reports as follows.

1 data and methods

1.1 clinical data

Group, 120 cases of patients, aged 15 to 71 years old, the average age of 34, 73 cases of male, female 47 cases, 68 cases of simple type chronic otitis media and cholesteatoma otitis media 52 cases.

1.2 operation method

The closed type - keep plane wall of mastoid tympanoplasty 102 cases, many options open mastoid area lesion - removed
