Introduction: Difficulties in mentalizing (i.e., the ability to reflect on self and others’ internal mental states, operationalized as reflective functioning [RF]; Fonagy et al., 2012) have been associated with psychological symptoms (Luyten et al., 2020), including somatic symptoms (Bizi et al., 2019). Therefore, the assessment of its dimensions may be clinically relevant for young patients with somatic symptoms, as with Primary Headache (PH), representing one of the most common somatic complaints in children and adolescents. Objectives: This study aimed to assess RF with a multi-method approach, exploring its relation with somatic symptoms. Methods: 48 adolescents diagnosed with PH (Mage=14.83, SD=2.81; 67% females) were recruited from an Italian Child Neuropsychiatry Clinic. RF was measured both through the Child and Adolescent Reflective Functioning (CRFS) applied to the Child Attachment Interview transcripts and the self-report Reflective Functioning Questionnaire (RFQ), while the Children’s Somatization Inventory (CSI-24) was used to measure the perceived severity of somatic symptoms. Results: Different relations with somatic symptoms depended on the method used to evaluate RF: no significant correlations were found with the CRFS subscales (General, Other, Self), while a negative significant correlation was found with the RFQ subscale Certainty about mental states (RFQ_C) (r=-.46, p=.016). All subscales of CRFS were negatively correlated with RFQ_C (p=.05), but not with the other RFQ subscale (Uncertainty about mental states; RFQ_U). Conclusions: This suggests that two measures may lead to different dimensions of the same construct, thus a multi-method assessment of RF would be advisable in clinical practice.

Disclosure: No significant relationships.

Introduction: ATR for children has successfully increase survival to adolescence. Health-related quality of life (HRQoL) is relevant to evaluate the impact of the disease on well-being in adolescents living with HIV (ALH). Kidscreen-52 questionnaire is validated in mexican adolescents to measure HRQoL.

Objectives: To evaluate health related quality of life in a sample of 22 mexican ALH
Methods: A sample of ALH in treatment at the HIV Clinic during 2021, were evaluated with Kidscreen-52 by a child psychiatrist. Statistics included non parametric tests and Cohen “d” and “r” size effect to compare T means between ALH and Kidscreen-52 standardized scores.

Results: Mean age:14.4±2.5. Gender: 11(50%)boys, 11(50%)girls. ALH showed significantly lower scores in all domains. Girls reported lower scores in physical well-being (p=0.047) and autonomy (p=0.023). Orphan ALH had lower scores in mood and emotions (p=0.021)

Conclusions: - HRQoL were significantly lower in ALH. -Girls showed significantly lower scores in physical well-being and autonomy. - ALH orphans showed significantly lower scores in mood and emotions domain
Disclosure: No significant relationships.

Introduction: Deficient emotion regulation is a common and impairing area of difficulty among children and adolescents with externalizing disorders. Emotion focused cognitive behavioral therapy ECBT is a form of CBT that is suggested to be employed to improve dysregulation of anxiety and other kind of emotions in anxious youth.

Objectives: Examine the efficacy of an Emotion-focused Cognitive-Behavioral Therapy (ECBT) inspired program on emotional regulation difficulties and behavioral problems in children and adolescents with externalizing disorders.
