Generalized Albanese morphisms

Georg Hein

Abstract

We define nef line bundles $L_r$ on a projective variety $X$ with the property that, for a curve $C \subset X$, the intersection $L_r.C$ is zero, if and only if the restriction morphism $\text{Hom}(\pi_1(X), U(r)) \to \text{Hom}(\pi_1(C), U(r))$ has finite image up to conjugation. This yields a rational morphism $X \rightarrow \text{Alb}_r(X)$ contracting those curves $C$ with $L_r.C = 0$. For $r = 1$ this is the Stein factorization of the Albanese morphism.

1. Introduction

The Albanese morphism $X \rightarrow \text{Alb}(X)$ of a complex algebraic variety $X$ can be characterized in different ways. The Stein factorization $\text{alb}_1 : X \rightarrow \text{Alb}_1(X)$ of this morphism can be described by those curves $C \subset Y$ which are contracted by $\text{alb}_1$ (see Proposition 2.4). Of interest to us is the following equivalence: a curve $\iota : C \rightarrow X$ is contracted by $\text{alb}_1$, if and only if the restriction morphism $\text{Hom}(\pi_1(X), U(1)) \to \text{Hom}(\pi_1(C), U(1))$ has finite image. A natural generalization would be a morphism $\text{alb}_r : X \rightarrow \text{Alb}_r(X)$ with the following property:

\[
\left( \begin{array}{l}
\text{a curve } \iota : C \rightarrow X \\
\text{is contracted by } \text{alb}_r 
\end{array} \right) \Leftrightarrow \left( \begin{array}{l}
\text{the restriction morphism} \\
\text{Hom}(\pi_1(X), U(r)) \to \text{Hom}(\pi_1(C), U(r)) \\
\text{has finite image modulo conjugation}
\end{array} \right).
\]

The aim of this paper is to give, at least birationally, such a morphism. Suppose the generalized Albanese morphism with the above property existed. Take an ample divisor class $H_r$ on $\text{Alb}_r(X)$. Define $L_r$ to be the pull back of the ample line bundle $\mathcal{O}_{\text{Alb}_r(X)}(H_r)$ to $X$. Eventually, we would obtain a nef line bundle $L_r$ on $X$ fulfilling the following:

\[
\left( \begin{array}{l}
\text{for a curve } C \rightarrow X \\
L_r.C = 0 \text{ holds}
\end{array} \right) \Leftrightarrow \left( \begin{array}{l}
\text{the restriction morphism} \\
\text{Hom}(\pi_1(X), U(r)) \to \text{Hom}(\pi_1(C), U(r)) \\
\text{has finite image modulo conjugation}
\end{array} \right).
\]

The main result of this paper is the construction of such a line bundle $L_r$ (§ 3) with that property (Theorem 4.2). This line bundle $L_r$ is a generalized Theta line bundle. Since we use various facts (see [DN89], [LPo96] and [Pop01]) about these bundles, a short résumé about these objects is presented in §§ 3.1–3.4. In § 5, the line bundle $L_r$ is used to construct a rational version $X \rightarrow \text{alb}_r(X)$ of a generalized Albanese morphism. This morphism is studied for algebraic surfaces in § 6. We begin this paper by reviewing the constructions of the classical Albanese morphism and describing its fibers in § 2.

In [Kol95], Kollár points out that the Albanese morphism can be regarded as a $U(1)$-version of the Shafarevich morphism. Hence, our morphism $\text{alb}_r$ could be regarded as a $U(r)$-version of it. Indeed, if the Shafarevich map $X \rightarrow \text{Sh}(X)$ existed, then $\text{alb}_r$ would factor through it. Katzarkov (see [Kat94] and [Kat97]) defined a reduction morphism for one representation $\pi_1(X) \rightarrow \text{GL}(r)$.

G. Hein

In the Kähler case, Eyssidieux [Eys04] showed that $\tilde{X}_r$, the universal covering of $X$ modulo those elements of $\pi_1(X)$ which are in the kernel of all $GL(r)$ representations, is holomorphically convex.

**Notation.** We work with schemes over the complex numbers. Since we need the restriction of (semi)stable vector bundles to curves, we are required to use the concept of Mumford-Takemoto or slope stability for vector bundles.

### 2. Two constructions for the Albanese variety

#### 2.1 The classical construction for the Albanese variety.

Here we assume that $X$ is a connected Kähler manifold. We define the Albanese variety $\text{Alb}(X)$ to be the quotient

$$\text{Alb}(X) := H^0(X, \Omega^1_X) / H_1(X, \mathbb{Z}).$$

If we choose a point $x_0 \in X(\mathbb{C})$, then we can define the Albanese morphism $\text{alb}_X : X \to \text{Alb}(X)$ by $x \mapsto \int_{\gamma_x}$ where $\gamma_x$ is a path connecting $x_0$ with $x$.

#### 2.2 The Pic$^0$(Pic$^0$)-description of $\text{Alb}(X)$.

Let $X$ be a smooth variety over an algebraically closed field $k$. We consider the Picard torus Pic$^0(X)$, i.e. the component of Pic($X$) containing $\mathcal{O}_X$. Furthermore, we consider a Poincaré bundle $L$ on $X \times \text{Pic}^0(X)$. This bundle is not unique. To normalize it we choose a point $x_0 \in X(k)$. If we require that $L_{|\{x_0\} \times \text{Pic}^0(X)} \cong \mathcal{O}_{\text{Pic}^0(X)}$, then the Poincaré bundle $L$ is uniquely determined. If we consider $L$ as a family of line bundles on Pic$^0(X)$ parametrized by $X$, then we obtain a morphism from $X$ to the Picard torus of Pic$^0(X)$:

$$\text{alb}_X : X \to \text{Pic}^0(\text{Pic}^0(X)) =: \text{Alb}(X).$$

#### 2.3 Both constructions coincide for smooth varieties over Spec(\mathbb{C}).

The use of the same notation in the above constructions is justified, because both coincide for a smooth projective variety over Spec(\mathbb{C}). This follows from the universal property of the Albanese variety and the duality between the Albanese variety and the Picard torus (cf. [GH78]). The following proposition describes the fibers of the Albanese morphism. Since it uses both descriptions (§§ 2.1 and 2.2), we have to assume that $X$/Spec(\mathbb{C}) is a smooth projective variety.

**Proposition 2.4.** (Description of the fibers of the Albanese morphisms $\text{alb}_X : X \to \text{Alb}(X)$, for a projective complex manifold $X$ (cf. [GH78, II.6])). If $\iota : Z \to X$ is a connected cycle in $X$, then the following conditions are equivalent:

(i) $Z$ is contained in a fiber of the morphism $\text{alb}_X$;

(ii) the image of $\iota_* : H_1(Z, \mathbb{Z}) \to H_1(X, \mathbb{Z})$ is finite;

(iii) the pull back morphism $\iota^* : H^0(X, \Omega^1_X) \to H^0(Z, \Omega^1_Z)$ is trivial;

(iv) if $\rho : \pi_1(X) \to U(1)$ is a representation of the fundamental group, then the restriction $\rho|_{\pi_1(Z)}$ has a finite image;

(v) if $L$ is a line bundle on $X \times S$, then the pull back $\iota^*L$ on $Z \times S$ is of the form $L_1 \boxtimes L_2$, for any Noetherian scheme $S$.

### 3. The line bundle $\mathcal{L}_r$

#### 3.1 The generalized Theta divisor, I: The determinant of cohomology.

Generalized Theta line bundles play a central role in this paper. Therefore, we repeat their definition, basic properties, as well as the construction of global sections of these line bundles. Let $C$ be a smooth
Generalized Albanese morphisms

projective curve of genus $g$. We assume that $E$ is a vector bundle on $S \times C$ with $S$ a connected Noetherian scheme. We denote the projections as

$$S \xrightarrow{q} S \times C \xrightarrow{p} C.$$  

For a geometric point $s \in S$, we let $E_s$ be the vector bundle $p_*(E \otimes q^*k(s))$ on $C$. Since $S$ is connected, the rank $r$ and the degree $d$ of $E_s$ do not depend on the choice of $s \in S$. We say that $E$ is a family of rank $r$ vector bundles of degree $d$ on $C$ parametrized by $S$. If all the vector bundles $E_s$ are semistable, then we obtain a morphism $S \to M_C(r,d)$ to the moduli space of $S$-equivalence classes of semistable vector bundles on $X$. Twisting $E$ with a line bundle $q^*L$ does not change this morphism. Therefore, the families $E$ and $E \otimes q^*L$ are considered to be equivalent.

For a coherent sheaf $F$ on $C$, we obtain a line bundle $\det(q(\mathcal{E} \otimes p^*F))$ on $S$ by taking the determinant of cohomology. This way, we obtain a morphism from the Grothendieck group $K(C)$ to the Picard group $\text{Pic}(S)$. Since $$\det(q((\mathcal{E} \otimes q^*L) \otimes p^*F)) \cong \det(q(\mathcal{E} \otimes p^*F)) \otimes L^{\otimes \chi(C,F \otimes \mathcal{E}_s)},$$
this line bundle is twist invariant whenever $\chi(C,F \otimes \mathcal{E}_s) = 0$. Thus, we consider the subgroup $K(C)^{\perp(r,d)}$ of $K(C)$ generated by coherent sheaves $F$ with $\chi(C,F \otimes \mathcal{E}_s) = 0$. The main result of Drezet and Narasimhan in [DN89] is that the line bundles $\det(q(\mathcal{E} \otimes p^*F))$ for $F \in K(C)^{\perp(r,d)}$ descend to line bundles on the moduli space $M_C(r,d)$, and the resulting morphism $K(C)^{\perp(r,d)} \to \text{Pic}(M_C(r,d))$ is surjective.

3.2 The generalized Theta divisor, II: The generalized Theta line bundle. We define the generalized Theta bundle first in the case when $d = 0$. We take a vector bundle $F$ of rank 2 and determinant $\omega_C$ on $C$. By the Riemann–Roch theorem for curves, we have $[F] \in K(C)^{\perp(0,0)}$. We denote the generalized Theta line bundle $\mathcal{O}_S(\Theta)$ to be the line bundle $\det(q(\mathcal{E} \otimes p^*F))^{-1}$ on $S$.

For $d$ arbitrary, we need a base point $s_0 \in S$. We choose a vector bundle $F$ of rank $2r$ and determinant $\omega_C^\otimes r \otimes \det(\mathcal{E}_{s_0})^{-\otimes 2}$. Again, we have $[F] \in K(C)^{\perp(r,d)}$ and define $\mathcal{O}_S(\Theta)$ to be the line bundle $\det(q(\mathcal{E} \otimes p^*F))^{-1}$ on $S$.

Remark. In both cases, we defined a multiple of the classical generalized Theta divisor. (When $d = 0$, we have defined the second power, whereas for $d$ arbitrary, we have defined the $2 \cdot (r,d)$ power of it.) However, to define the appropriate root, further choices are involved.

3.3 The generalized Theta divisor, III: Global sections. Let $\mathcal{O}_S(\Theta) = \det(q(\mathcal{E} \otimes p^*F))^{-1}$ be the Theta line bundle and $m$ a natural number. Suppose we are given a finite number of vector bundles $\{G_i\}_{i=1,...,n}$ on $C$ with $[G_i] = m[F]$ in $K(C)$. The following construction of Le Potier (see [LPo06]) assigns each $G_i$ a global section $\theta_{G_i}$ in $\Gamma(\mathcal{O}_S(m\Theta)))$. First, we take a line bundle $N$ on $C$ such that $G_i \otimes N$ is globally generated for all $i$, and $q_*(\mathcal{E} \otimes p^*N^{-1}) = 0$. Let $R := \text{rk}(G_i)$. Therefore, we have surjections $(N^{-1})^{\otimes R} \xrightarrow{\pi_i} G_i$. The kernel of $\pi_i$ is the line bundle $M := \det(G_i)^{-1} \otimes N^{-\otimes (R-1)}$. Since $[G_i] = [G_j]$ in $K(C)$, the determinant line bundles of $G_i$ and $G_j$ coincide. Hence, the line bundle $M$ is independent of $i$. From the short exact sequence $0 \to M \xrightarrow{\alpha_i} (N^{-1})^{\otimes (R+1)} \xrightarrow{\pi_i} G_i \to 0$, we pass to the long exact sequence

$$0 \to q_*(\mathcal{E} \otimes p^*G_i) \to R^1 q_*(\mathcal{E} \otimes p^*M) \xrightarrow{R^1(\alpha_i)} R^1 q_*(\mathcal{E} \otimes p^*(N^{-1})^{\otimes (R+1)}) \to R^1 q_*(\mathcal{E} \otimes p^*G_i) \to 0.$$

By construction, $R^1(\alpha_i)$ is a homomorphism of vector bundles of the same rank. Thus, we obtain a section

$$\theta_{G_i} := \det(R^1(\alpha_i)) \in \Gamma(\det(R^1 q_*(\mathcal{E} \otimes p^*(N^{-1})^{\otimes (R+1)})) \otimes (R^1 q_*(\mathcal{E} \otimes p^*M))^{-1}.$$
The sections $\theta_{G_i}$ are sections of the line bundle $\mathcal{O}_S(m\Theta)$. The base change theorem yields that the vanishing loci $V(\theta_{G_i})$ are given by
\[ V(\theta_{G_i}) = \{ s \in S \mid H^*(C, G_i \otimes \mathcal{E}_s) \neq 0 \}. \]

### 3.4 The generalized Theta divisor, IV: Base point freeness.

One the one hand, it is obvious that any pair $E$ and $F$ of vector bundles on $C$ with $H^*(C, E \otimes F) = 0$ is a pair of semistable vector bundles. On the other hand, a result of Popa (see [Pop01]) says that, for any semistable vector bundle $E$ on $C$, and any integer $a \geq \text{rk}(E)$, there exists a vector bundle $F$ on $C$ with $\text{rk}(F) = 2a \ \text{rk}(E)$ and $\det(F) = \omega_C^{2a} \otimes \det(\mathcal{E}_a)_{\otimes 2a}$ where $\mathcal{E}_a$ is an arbitrary bundle with the same rank and degree as $E$. Thus, for $a \geq r$, the base points of the sections in $\mathcal{O}_S(a\Theta)$ described in §3.3 are the points $s \in S$ parametrizing unstable vector bundles. Drézet and Narasimhan [DN89] showed that the generalized Theta line bundle is an ample line bundle on the moduli space of $S$-equivalence classes of semistable vector bundles. Note that this allows us to distinguish $S$-equivalence classes $[E_1]$ and $[E_2]$ whenever we have a vector bundle $G$ with $H^*(E_1 \otimes G) = 0$ and $H^*(E_2 \otimes G) \neq 0$.

### 3.5 The setup.

We fix a smooth projective variety $X$ of dimension $n$ with a very ample line bundle $\mathcal{O}_X(H)$ and a positive integer $r$. Furthermore, we choose a geometric point $x_0 \in X$. Let $M_r = M_X(r, 0, 0, \ldots, 0)$ be the moduli space of $S$-equivalence classes of slope semistable rank $r$ bundles $E$ with trivial Chern classes in $H^*(X, \mathbb{Z})$. If $E$ is a vector bundle parametrized by $M_r$, then we write $[E]$ for the corresponding point in $M_r(C)$. By the theorem of Uhlenbeck and Yau (see [UY86]), $M_r$ parametrizes flat vector bundles on $X$ or representations of $\pi_1(X)$ in $U(r)$ modulo conjugation. This implies that, for $[E] \in M_r$, the restriction $E|_C$ of $E$ to any curve $C \subset X$ is a semistable vector bundle. This implication is the reason why we have to restrict ourselves to the moduli space of flat vector bundles on $X$. Moreover, $M_r$ is a projective scheme provided that we pass to $S$-equivalence classes of semistable bundles. This means we identify any vector bundle $E$ in a short exact sequence $0 \to E' \to E \to E'' \to 0$ of slope zero bundles with the direct sum $E' \oplus E''$. Hereafter, we will use the symbol $M_r$ (or $M_r(X)$) for the projective moduli space of $S$-equivalence classes of slope semistable bundles on $X$.

### 3.6 The line bundle $\mathcal{O}_M(D_H)$.

Using the polarization $H$ on $X$, we can define a polarization $D_H$ on $M$. We choose a faithfully flat morphism $\psi: \tilde{M} \to M$ such that we have a universal sheaf $\tilde{E}$ on $\tilde{M} \times X$. This means that, for any point $\tilde{m} \in \tilde{M}$, the sheaf $\tilde{E}_{\tilde{m}} := \tilde{E}|_{\tilde{m} \times X}$ is a sheaf which belongs to the $S$-equivalence class given by $\psi(\tilde{m})$. The theory of Quot schemes gives the existence of such morphisms. Let $C = H_1 \cap H_2 \cap \cdots \cap H_{n-1}$ be a complete intersection of $n - 1$ divisors $H_i \subset |H|$. Furthermore, we take a rank 2 vector bundle $F$ on $C$ with $\det(F) \cong \omega_C$. We consider the following morphisms.

\[ \begin{array}{ccc} \tilde{M} \times X & \xrightarrow{\psi} & M \times X \\ \downarrow \psi & & \downarrow \psi \\ \tilde{M} & \xrightarrow{\tilde{p}} & M \\ \downarrow \tilde{q} & & \downarrow q \\ X & \xrightarrow{p} & M \end{array} \]

On $\tilde{M}$, we define the line bundle $\mathcal{O}(\tilde{D}_H)$ to be the determinant of cohomology
\[ \mathcal{O}_{\tilde{M}}(\tilde{D}_H) := \det(\tilde{q}_*(\tilde{E} \otimes \tilde{p}^*F))^{-1}. \]

This line bundle descends to $M$, i.e. there exists a line bundle $\mathcal{O}_M(D_H)$ and an isomorphism $\mathcal{O}_{\tilde{M}}(\tilde{D}_H) \cong \psi^*\mathcal{O}_M(D_H)$. Furthermore, the line bundle $\mathcal{O}_M(D_H)$ does not depend on the choice of the morphism $\psi: \tilde{M} \to M$ (see [DN89]).
Generalized Albanese morphisms

Lemma 3.7. The first Chern class $\tilde{D}_H := c_1(\mathcal{O}_M(\tilde{D}_H))$ is given by

$$\tilde{D}_H = \tilde{q}_*(2c_2(\tilde{E}) - c_1^2(\tilde{E})), p^*H^{n-1}).$$

In particular, we have $D_{aH} = a^{n-1}D_H$.

Proof. This is straightforward computation using the Grothendieck–Riemann–Roch formula

$$\tilde{D}_H = -[\tilde{q}_*(\text{ch}(\tilde{E}) \cdot \text{Td}(\tilde{q}) \cdot p^*\text{ch}(F))]_1,$$

and the equalities

$$\text{ch}(\tilde{E}) = r + c_1(\tilde{E}) + \frac{c_1^2(\tilde{E}) - 2c_2(\tilde{E})}{2} + \cdots,$$

$$\text{Td}(\tilde{q}) = p^*\text{Td}(X) = 1 - \frac{p^*K_X}{2} + \cdots,$$

$$\text{ch}(F) = \text{ch}(\mathcal{O}_X \oplus \mathcal{O}_X(K_X + (n-1)H)) \cdot \text{ch}(\mathcal{O}_H)^{n-1} = 2H^{n-1} + K_XH^{n-1}.$$

Whereas the first two equalities are standard, the last equality follows from the adjunction formula and the fact that a vector bundle $F$ on a curve $C$ is determined in the Grothendieck group $K(C)$ by its rank and determinant.

Lemma 3.8. The line bundle $\mathcal{O}_{M_r}(a \cdot D_H)$ is base point free for $a \geq r^2$.

Proof. This is just the statement of Popa’s theorem given in §3.4.

Lemma 3.9. The line bundle $\mathcal{O}_{M_r}(D_H)$ is ample.

Proof. The proof uses the fact that, on a projective variety of dimension at least two, the vector bundles $E$ and $E'$ with the same Hilbert polynomial are isomorphic, if and only if their restrictions to a sufficiently big ample divisor $H$ are isomorphic. This follows from the following long exact sequence.

$$\text{Hom}(E, E'(-H)) \longrightarrow \text{Hom}(E, E') \longrightarrow \text{Hom}(E, E'|_{H}) \longrightarrow \text{Ext}^1(E, E'(-H)) \longrightarrow \text{Hom}(E'|_{H}, E'|_{H}) \longrightarrow \text{H}^1(E' \otimes E'(-H))$$

If we have a bounded family of vector bundles as in the case of those parametrized by $M_r$, then we can choose a divisor $H$ such that, for any two bundles in this family, the cohomology groups on the left- and right-hand sides vanish.

The restriction theorem of Mehta and Ramanathan (see [MR84]) tells us that, for a semistable vector bundle $E$ and $H$ big enough, the formation of graded objects commutes with restriction to $H$. Thus, we obtain an embedding $M_r = M_r(X) \longrightarrow M_r(H)$. Repeating the argument, we end up with an embedding $M_r \longrightarrow M_r(C)$ for a complete intersection curve $C$. By Lemma 3.7, we may assume that this curve $C$ is the curve we considered in the construction of $\mathcal{O}(D_H)$.

By construction, $\mathcal{O}(D_H)$ is the pull back of the generalized Theta line bundle on $M_r(C)$. This line bundle is known to be ample by the work of Drezet and Narasimhan (see [DN89]). Thus, the lemma holds.

3.10 The families $\mathcal{E}_{r,i}$. Let $M_r^{\text{red}} = \bigcup_{i=1}^l M_{r,i}$ be the decomposition of the reduced scheme underlying $M_r$ into its irreducible components, and let $\tilde{M}_{r,i}$ be the normalization of the component $M_{r,i}$. We have a morphism $\alpha_i : \tilde{M}_{r,i} \rightarrow M_r$ and consider the globally generated line bundle $\mathcal{O}(r^2 \cdot D_H)$. Let $C_{r,i}$ be the intersection of $\dim(\tilde{M}_{r,i}) - 1$ general global sections of $N_{r,i}$. By Bertini’s theorem, $C_{r,i}$ can be assumed to be a smooth irreducible curve.
Thus, by Langton’s theorem (see [Lan75]), we have a universal vector bundle \( E_{r,i} \) on \( C_{r,i} \times X \). If the universal vector bundle \( E_M \) on \( M_r \times X \) existed, then \( E_{r,i} \) would be the pull back of this bundle to \( C_{r,i} \times X \).

### 3.11 The line bundle \( L_{r,i} \).

We consider the vector bundle \( E_{r,i} \) on \( C_{r,i} \times X \) and the morphisms

\[
C_{r,i} \xrightarrow{q} C_{r,i} \times X \xrightarrow{p} X.
\]

We define the line bundle \( N_{r,i} \) on the curve \( C_{r,i} \) by \( N_{r,i} := \text{det}(E_{r,i}|_{C_{r,i} \times \{x_0\}}) \). Let \( G_{r,i} \) be a vector bundle on \( C_{r,i} \) with \( \text{rk}(G_{r,i}) = 2r \), and \( G_{r,i} \cong \omega_{E_{r,i}} \otimes N_{r,i}^{-2} \). Similar to the definition of \( \mathcal{O}_{M_r}(D_H) \) in §3.6, we define the line bundle by

\[
L_{r,i} := \text{det}(p_1(E_{r,i} \otimes q^*G_{r,i}))^{-1}.
\]

### 3.12 Remark.

Unfortunately, in contrast to \( \mathcal{O}_{M_r}(D_H) \), the line bundle \( L_{r,i} \) is not independent of the choices. We next give an example for this dependence on the choice of the family \( E_{r,i} \).

Let \( X \) be a curve, and \( E_{r,i} \) be a family of degree zero vector bundles on \( X \) parametrized by \( C_{r,i} \). For any \( c \in C_{r,i} \), we consider the vector bundle \( E_c := E_{r,i}|_{c} \times X \). Furthermore, we assume that \( E_c \) is not stable. Thus, we have a short exact sequence

\[
0 \rightarrow E'_c \rightarrow E_c \rightarrow E''_c \rightarrow 0
\]

of degree zero vector bundles on \( X \). Denote by \( E'_{r,i} \) the kernel of the natural surjection \( E_{r,i} \rightarrow E'_c \). The families \( E'_{r,i} \) and \( E_{r,i} \) parametrize the same \( S \)-equivalence classes of vector bundles on \( X \). A straightforward computation shows that the resulting line bundles \( L'_{r,i} \) and \( L_{r,i} \) fulfill

\[
L'_{r,i} = \text{det}(E'_c)^{2\text{rk}(E''_c)} \otimes \text{det}(E''_c)^{-2\text{rk}(E'_c)} \otimes L_{r,i}.
\]

Thus, we can only hope that the numerical type of \( L_{r,i} \) is well defined. This is the case, as we will see in the next section (see Corollary 4.4).

### 3.13 We end this section by defining the line bundle \( L_r \) on \( X \) by

\[
L_r := \bigotimes_{i=1}^{l} L_{r,i}.
\]

### 4. Properties of the line bundles \( L_r \)

#### 4.1 Relations defined by nef line bundles.

Let \( L \) be a nef line bundle on a proper variety \( X \). This line bundle defines an equivalence relation \( \sim_L \) on the geometric points of \( X \) as follows:

\[
x \sim_L x' \iff \begin{cases} 
\text{there exists a closed curve } C \subset X \\
\text{with } x \in C, x' \in C, \text{ and } \mathcal{L}C = 0 \end{cases}
\]

We define the relation \( \preceq \) on nef line bundles by: the condition \( L_1 \preceq L_2 \) holds if for any curve \( C \subset X \) the inequality \( L_1.C > 0 \) implies \( L_2.C > 0 \).

We write \( L_1 \prec L_2 \) if \( L_1 \preceq L_2 \) holds, and there exists a curve \( C \subset X \) with \( L_1.C = 0 \) and \( L_2.C > 0 \). If \( L_1 \preceq L_2 \) holds, then the relation \( \sim_{L_2} \) is contained in \( \sim_{L_1} \), i.e. if \( x \sim_{L_2} x' \), then we have \( x \sim_{L_1} x' \). Whenever both relations \( L_1 \preceq L_2 \) and \( L_2 \preceq L_1 \) hold, we write \( L_1 \sim L_2 \). This means that the relations \( \sim_{L_1} \) and \( \sim_{L_2} \) coincide.

If we have a chain \( L_0 \prec L_1 \prec \cdots \prec L_k \) of nef line bundles, then we have strict inclusions \( (\text{NE}(X) \cap L_1^k) \subset (\text{NE}(X) \cap L_{k-1}^k) \subset \cdots \subset (\text{NE}(X) \cap L_0^k) \) in the cone of curves. Since the orthogonal complements \( L_i^\perp \) are linear subspaces of \( H^2(X, \mathbb{R}) \), we deduce that \( k \leq \rho(X) = \dim(\text{NE}(X)) \).
THEOREM 4.2. The line bundle $L_{r,i}$ is nef, i.e. for any morphism $\iota : Y \to X$ of a smooth curve $Y$ to $X$, the degree of the line bundle $\iota^*L_{r,i}$ is non-negative. Furthermore, if the degree of $\iota^*L_{r,i}$ equals zero, then for all geometric points $y_1$ and $y_2$ of $Y$ there exists an isomorphism $\mathcal{E}_{C_{r,i} \times \{y_1\}} \cong \mathcal{E}_{C_{r,i} \times \{y_2\}}$, and all the vector bundles on $Y$ parametrized by $C_{r,i}$ are $S$-equivalent.

Proof. We divide the proof into eight steps.

Step 1: Reduction to the case where $X$ is a smooth projective curve. Since all the vector bundles parametrized by $M_r$ restrict to semistable bundles on every closed subscheme $\iota : Y \to X$ of $X$, the pull back $(id \times \iota)^*\mathcal{E}_{r,i}$ is a family of semistable rank $r$ vector bundles on $Y$ parametrized by $C_{r,i}$. Since the determinant of cohomology commutes with base change, we may assume $X = Y$. Thus, we consider the vector bundle $\mathcal{E}_{r,i}$ on the surface $C_{r,i} \times X$ and the following morphisms to smooth curves:

$$C_{r,i} \xymatrix{ q \ar[r]^-{q} & C_{r,i} \times X \ar[r]^-p & X.}$$

Step 2: The line bundles $L_1$ and $L_2 := L_{r,i}$. Let $F$ be a vector bundle on $X$ with $rk(F) = 2r$ and $\det(F) = \omega_X$. For a point $x_0 \in X$, we set $N_{r,i} := \det(\mathcal{E}_{r,i}|_{C_{r,i} \times \{x_0\}})$. Let $G$ be a vector bundle on $C_{r,i}$ of rank $2r$ with $\det(G) = \omega_{C_{r,i}} \otimes N_{r,i}^{-2}$. We set $L_1 := \det(q(\mathcal{E}_{r,i} \otimes p^*F))^{-1}$ and $L_2 := \det(p_!(\mathcal{E}_{r,i} \otimes q^*G))^{-1}$. The nefness property of $L_{r,i}$ is equivalent to $\deg(L_2) \geq 0$.

The line bundle $L_2$ is the generalized Theta line bundle constructed in §3.2 for the family $\mathcal{E}_{r,i}$ of vector bundles on $C_{r,i}$ parametrized by $X$ with distinguished point $x_0$. The line bundle $L_1$ is the $r$-fold power of the generalized Theta line bundle from §3.2 for the family $\mathcal{E}_{r,i}$ of vector bundles of degree zero on $X$ parametrized by $C_{r,i}$.

Step 3: $\deg(L_1) = \deg(L_2)$. We use the Grothendieck–Hirzebruch–Riemann–Roch theorem to compute the degrees of the line bundles $L_1$ and $L_2$. Let us fix the notation before doing so. By $c_0$ and $x_0$, we denote two geometric points of $C_{r,i}$ and $X$. We use $F_p$ and $F_q$ to name the fibers $p^{-1}(x_0)$ and $q^{-1}(c_0)$. The genera of $C_{r,i}$ and $X$ we denote by $g_C$ and $g_X$. Since we are only interested in the degrees, we may assume $\omega_X = \mathcal{O}_X((2g_X - 2)x_0)$ and $\omega_{C_{r,i}} = \mathcal{O}_X((2g_C - 2)c_0)$. For the same reason, we have $\text{ch}(F) = 2r + 2r(g_X - 1)x_0$ and $\text{ch}(G) = 2r + (2r(g_C - 1) - 2\int_{C_{r,i} \times X}(F_p.c_1(\mathcal{E}_{r,i})))c_0$. Furthermore, let $\text{Td}(C_{r,i}) = 1 - (g_X - 1)c_0$ and $\text{Td}(X) = 1 - (g_C - 1)x_0$ be the (numerical) Todd classes. Then we have

$$\deg(L_1) = -\int_{C_{r,i}}\text{ch}(q(\mathcal{E}_{r,i} \otimes p^*F))$$

$$= -\int_{C_{r,i} \times X}\text{ch}(\mathcal{E}_{r,i} \otimes p^*F)p^*\text{Td}(X)$$

$$= -\int_{C_{r,i} \times X}\text{ch}(\mathcal{E}_{r,i})p^*\text{ch}(F)p^*\text{Td}(X)$$

$$= -\int_{C_{r,i} \times X}\text{ch}(\mathcal{E}_{r,i})p^*(\text{ch}(F)\text{Td}(X))$$

$$= -\int_{C_{r,i} \times X}\left(r + c_1(\mathcal{E}_{r,i}) + \frac{c_1^2(\mathcal{E}_{r,i}) - 2c_2(\mathcal{E}_{r,i})}{2}\right)p^*(2r)$$

$$= r \cdot \int_{C_{r,i} \times X}(2c_2(\mathcal{E}_{r,i}) - c_1^2(\mathcal{E}_{r,i})).$$

725
The scheme parametrizes a family of $X$ vector bundles of degree zero, the intersection number $\int_{C_{r,i} \times X} F_q \cdot c_1(\mathcal{E}_{r,i})$ equals zero. Thus, we end up with the claimed equality.

**Step 4:** $L_1^{\otimes r}$ is globally generated. Thus, $\deg(L_2) = \deg(L_1) \geq 0$. This is a direct consequence of Lemma 3.8.

To prove $\deg(L_1) \geq 0$, we need fewer premises. Indeed, if at least one point of $c \in C_{r,i}$ parametrizes a semistable vector bundle $\mathcal{E}_c$ on $X$, then a power of $L_1$ has a non-trivial section $\theta_G$ (see §§3.3 and 3.4) which is what we need.

If the degree of $L_1$ is positive, then we consider two points $s_1$, $s_2$ of $C_{r,i}$ with the property that a section $\theta_G$ vanishes at $s_1$ but not at $s_2$. It follows from the remark at the end of §3.4 that the $X$ vector bundles parametrized by $s_1$ and $s_2$ are not $S$-equivalent.

From now on, we assume that the degrees of $L_1$ and $L_2$ are zero. For the following steps see also the proof of Theorem I.4 in Faltings’ article [Fal93] or for the simpler rank 2 case see [Hei99, Theorem 3.4].

**Step 5:** For any two geometric points $P$ and $Q$ of $X$, the vector bundles $\mathcal{E}_{r,i}|_{C_{r,i} \times \{P\}}$ and $\mathcal{E}_{r,i}|_{C_{r,i} \times \{Q\}}$ are isomorphic. We show that, given a point $P \in X$, for almost all points $Q \in X$, we have an isomorphism between $\mathcal{E}_{r,i}|_{C_{r,i} \times \{P\}}$ and $\mathcal{E}_{r,i}|_{C_{r,i} \times \{Q\}}$. From this statement, the assertion of step 5 follows immediately. Fix a geometric point $c_0 \in C_{r,i}$. Let $\mathcal{E}_{c_0} := \mathcal{E}_{r,i}|_{\{c_0\} \times X}$ be the semistable vector bundle on $X$ parametrized by $c_0$. Take a vector bundle $F_P$ on $X$ such that $H^*(X, F_P \otimes \mathcal{E}_{c_0}) = 0$. Such a bundle exists as we have seen in §3.4. Moreover, it defines a global section $\theta_{F_P}$ in a power of $L_1$ which does not vanish at $c_0$. Since $\deg(L_1) = 0$, this section has an empty vanishing divisor. The description of the vanishing divisor of $\theta_{F_P}$ (see §3.3) implies that $H^*(X, F_P \otimes \mathcal{E}_{r,i}|_{\{c\} \times X}) = 0$ for all points $c \in C_{r,i}$. This implies that $R^*q_*(\mathcal{E}_{r,i} \otimes p^*F_P)$ is zero. Now we consider a non-trivial extension $E$ in $\text{Ext}^1(k(P), F_P)$:

\[(S_P) \quad 0 \to F_P \to E \xrightarrow{\pi_P} k(P) \to 0.\]

The scheme $\mathbb{P}(F)$ parametrizes surjections $\pi : F \to k(Q)$ from $F$ to torsion sheaves of length one. The subset of $\mathbb{P}(F)$ where $H^*(X, \ker(\pi) \otimes \mathcal{E}_{c_0}) = 0$ is open and not empty because it contains $\pi_P$. Thus, for a general point $Q$ of $X$, there exists a short exact sequence

\[(S_Q) \quad 0 \to F_Q \to F \to k(Q) \to 0\]

with $H^*(X, F_Q \otimes \mathcal{E}_{c_0}) = 0$. Applying the functor $R^*q_*(\mathcal{E}_{r,i} \otimes p^*(-))$ to the short exact sequences $(S_P)$ and $(S_Q)$, we obtain that $q_*(p^*F \otimes \mathcal{E}_{r,i})$ is isomorphic to $\mathcal{E}_{r,i}|_{C_{r,i} \times \{P\}}$ and to $\mathcal{E}_{r,i}|_{C_{r,i} \times \{Q\}}$ as well.

Thus, all the vector bundles on $C_{r,i}$ parametrized by $X$ are isomorphic to the vector bundle $G := q_*(p^*F \otimes \mathcal{E}_{r,i})$.

**Step 6:** The filtration $F^*(\mathcal{E}_{r,i})$ on the vector bundle $\mathcal{E}_{r,i}$. If we consider the Harder–Narasimhan filtration on $G := q_*(p^*F \otimes \mathcal{E})$, then the graded summands need not be simple bundles. We consider a slight generalization by taking $G_1$ to be a subsheaf of $G$ which is stable of maximal possible slope. Defining $F^1(\mathcal{E}_{r,i}) := G_1 \boxtimes p_* \text{Hom}(q^*G_1, \mathcal{E}_{r,i})$, and $F^1(\mathcal{E}_{r,i}) := \pi_1^{-1}(F_1(\mathcal{E}_{r,i}/F^1(\mathcal{E}_{r,i})))$, where $\pi_1$
is the surjection from \( \mathcal{E}_{r,i} \to \mathcal{E}_{r,i}/F^1(\mathcal{E}_{r,i}) \), we obtain a filtration \( 0 = F^0(\mathcal{E}_{r,i}) \subset F^1(\mathcal{E}_{r,i}) \subset \cdots \subset F^k(\mathcal{E}_{r,i}) = \mathcal{E}_{r,i} \) on \( \mathcal{E}_{r,i} \) with the property that the \( j \)th graded object \( \text{gr}^j(\mathcal{E}_{r,i}) := F^j(\mathcal{E}_{r,i})/F^{j-1}(\mathcal{E}_{r,i}) \) is of the form \( G_j \boxtimes F_j \). By definition the slopes \( \mu_j := \mu(G_j) = \deg(G_j)/\text{rk}(G_j) \) form a decreasing sequence \( \mu_1 \geq \mu_2 \geq \cdots \geq \mu_k \).

Restricting the filtration \( F^*(\mathcal{E}_{r,i}) \) to a fiber \( p^{-1}(x) \) of \( p \), we obtain a filtration of \( G \) which does not depend on the choice of \( x \in X \). The restricted vector bundle \( F^j(\mathcal{E}_{r,i})|_{p^{-1}(x)} \) appears in the Harder–Narasimhan filtration of \( G \), if and only if \( \mu_j > \mu_{j+1} \). Therefore, we use \( \text{HNF}^*(\mathcal{E}_{r,i}) \) to name the subfiltration of the filtration \( F^*(\mathcal{E}_{r,i}) \) consisting of those \( F^j(\mathcal{E}_{r,i}) \) with \( \mu_j > \mu_{j+1} \).

**Step 7: Numerical invariants of the filtration** \( F^*(\mathcal{E}_{r,i}) \). In the Grothendieck group \( K(C_{r,i} \times X) \), we can identify \( \mathcal{E}_{r,i} \) with the direct sum of the graded objects \( \text{gr}^j(\mathcal{E}_{r,i}) \):

\[
[\mathcal{E}_{r,i}] = \sum_{j=1}^{k} [\text{gr}^j(\mathcal{E}_{r,i})] = \sum_{j=1}^{k} [G_j \boxtimes F_j].
\]

Since the Chern character of the product \( G_j \boxtimes F_j \) is given by

\[
\text{ch}(G_j \boxtimes F_j) = q^* \text{ch}(G_j)p^* \text{ch}(F_j) = \text{rk}(G_j) \cdot \text{rk}(F_j) + \text{rk}(G_j)p^*c_1(F_j) + \text{rk}(F_j)q^*c_1(G_j) + p^*c_1(F_j)q^*c_1(G_j),
\]

we deduce the equality \( \int_{C_{r,i} \times X} \text{ch}(\mathcal{E}_{r,i}) = \sum_{j=1}^{k} \deg(G_j) \cdot \deg(F_j) \). In step 3, we identified the left hand side with \( -1/(2r) \deg(L) \). Thus, we have

\[
\sum_{j=1}^{k} \deg(G_j) \cdot \deg(F_j) = 0. \tag{1}
\]

The degree \( \deg_X(F^j(\mathcal{E}_{r,i})|_{q^{-1}(c)}) \) of \( F^j(\mathcal{E}_{r,i}) \), restricted to a fiber of \( q \), is given by

\[
\deg_X(F^j(\mathcal{E}_{r,i})|_{q^{-1}(c)}) = \sum_{m=1}^{j} \text{rk}(G_m) \cdot \deg(F_m).
\]

Since the restriction of \( \mathcal{E}_{r,i} \) to a fiber of \( q \) is semistable of degree zero, we deduce that

\[
A_j := \sum_{m=1}^{j} \text{rk}(G_m) \cdot \deg(F_m) \leq 0, \tag{2}
\]

and \( A_k = 0 \). Having in mind that \( \mu_j := \deg(G_j)/\text{rk}(G_j) \), we rewrite (1) as

\[
0 = \sum_{j=1}^{k} \mu_j \cdot \text{rk}(G_j) \cdot \deg(F_j) = \sum_{j=1}^{k} A_j \cdot (\mu_j - \mu_{j+1}),
\]

where we set \( \mu_{k+1} = 0 \). The inequalities (2) and \( \mu_j \geq \mu_{j+1} \) imply, therefore, that \( A_j = 0 \) whenever \( \mu_j > \mu_{j+1} \).

**Step 8: \( S \)-equivalence of all bundles parametrized by \( C_{r,i} \).** The conclusion of the preceding steps is that each quotient \( \text{gr}^j_{\text{HNF}} := \text{HNF}^j(\mathcal{E}_{r,i})/\text{HNF}^{j-1}(\mathcal{E}_{r,i}) \) is, on the one hand, semistable of degree zero when restricted to the fibers of \( q \). On the other hand, when restricting to a fiber of \( p \) we obtain a vector bundle which is an extension of stable vector bundles of the same slope. Thus, the restriction of \( \text{gr}^j_{\text{HNF}} \) to both families of fibers is semistable.

If we construct the Theta line bundle associated to \( \text{gr}^j_{\text{HNF}} \), then we obtain a line bundle of degree zero on \( X \). This follows from the computation in step 7. Now we have a semistable family of vector bundles parametrized by \( X \) with degree zero Theta divisor. The argument of step 5 yields that all the bundles parametrized by the family \( \text{gr}^j_{\text{HNF}} \) on \( X \) are isomorphic.
In other words, the direct sum \( \bigoplus_{j=1}^{l} \mathfrak{g}_{\text{HFN}}^{j} \) of the graded objects gives the same direct sum of semistable vector bundles of degree zero on each fiber of \( q \). In short, all vector bundles parametrized by \( C_{r,i} \) are \( S \)-equivalent. The proof of Theorem 4.2 is complete.

**Theorem 4.3.** Let \( \iota : Y \to X \) be a morphism of a smooth curve \( Y \) to \( X \). We obtain a morphism \( \iota_{M_{r,i}} : \hat{M}_{r,i}(X) \to M_{r}(Y) \) by the pull back of vector bundles. The following two conditions are equivalent:

(i) the degree of \( \iota^{*}L_{r,i} \) is zero;

(ii) the morphism \( \iota_{M_{r,i}} \) maps \( \hat{M}_{r,i}(X) \) to a point.

**Proof.** We consider the morphisms \( C_{r,i} \xrightarrow{\alpha} \hat{M}_{r,i}(X) \xrightarrow{\iota_{M_{r,i}}} M_{r}(Y) \). Theorem 4.2 implies that the degree of \( \iota^{*}L_{r,i} \) is zero, if and only if \( \iota_{M_{r,i}}(C_{r,i}) \) is a point. This implies the theorem because \( \hat{M}_{r,i}(X) \) is irreducible, and \( C_{r,i} \) is the intersection of ample divisors.

**Corollary 4.4.** The equivalence classes of the nef line bundles \( L_{r,i} \) and \( L_{r} \) with respect to \( \sim \) (see \( \S \) 4.1) depend neither on the choice of \( C_{r,i} \subset \hat{M}_{r,i} \) nor on the choice of the vector bundle \( E_{r,i} \) on \( C_{r,i} \times X \). Furthermore, these equivalence classes are independent of the chosen polarization \( H \) on \( X \).

**Corollary 4.5.** \( C4.5 \) The line bundle \( L_{r} \) on \( X \) is nef. For a morphism \( \iota : Y \to X \) of a smooth curve \( Y \) to \( X \), we have \( \deg(\iota^{*}L_{r}) = 0 \), if and only if the morphism \( M_{r}(X) \to M_{r}(Y) \) is locally constant.

**Proposition 4.6.** The line bundles \( \{L_{r}\}_{r \in \mathbb{R}} \) satisfy the inequality \( L_{r_{i}} \leq L_{r_{j}} \), for \( r_{i} \leq r_{j} \). There exists a number \( R \in \mathbb{N} \) such that \( L_{r} \preceq L_{R} \) for all \( r \).

**Proof.** If \( r_{1} < r_{2} \), then we have an embedding of moduli spaces \( M_{r_{1}} \to M_{r_{2}} \) given by \( [E] \mapsto [E \oplus E_{X}^{\oplus(r_{2}-r_{1})}] \). Thus, we deduce from Theorem 4.3 that the inequality \( L_{r_{1}} \preceq L_{r_{2}} \) holds. We have seen in \( \S \) 4.1 that in the chain \( L_{1} \preceq L_{2} \preceq \cdots \preceq L_{r} \preceq \cdots \) there are at most \( \rho(X) \) strict inclusions. This proves the second assertion of the proposition.

### 4.7 The line bundle \( L_{\infty} \).

We use the name \( L_{\infty} \) for the line bundle \( L_{R} \) of the above proposition. When referring to this line bundle, we should be aware that \( L_{\infty} \) is only a class in \( \{ \text{nef line bundles} \}/\sim \). Considering these equivalence classes (with the discrete topology), we have \( \lim_{r \to \infty} L_{r} \sim L_{\infty} \).

In the following theorem, we have summarized the results of this section.

**Theorem 4.8** (Properties of the line bundles \( L_{r} \)). Let \( X \) be a projective variety. We have an infinite sequence of nef line bundles \( L_{1} \preceq L_{2} \preceq \cdots \preceq L_{r} \preceq \cdots \) and a nef limit line bundle \( L_{\infty} \) with \( \lim_{r \to \infty} L_{r} \sim L_{\infty} \) on \( X \) such that for any morphism \( \iota : Y \to X \) of a smooth curve \( Y \) to \( X \) the following conditions are equivalent:

(i) \( \deg(\iota^{*}L_{r}) = 0 \);

(ii) the restriction morphism \( M_{r}(X) \to M_{r}(Y) \) is locally constant;

(iii) for any connected scheme \( Z \) and every vector bundle \( \mathcal{E} \) on \( Z \times X \) parametrizing semistable rank \( r \) vector bundles on \( X \) with trivial Chern classes, the pull back \( (\text{id}_{Z} \times \iota)^{*}\mathcal{E} \) parametrizes only one \( S \)-equivalence class on \( Y \);

(iv) modulo conjugation only finitely many \( U(r) \) representations of \( \pi_{1}(Y) \) are induced by those of \( \pi_{1}(X) \).

728
5. The generalized Albanese morphisms

5.1 The construction of the generalized Albanese morphism. If \( L_r \) or some power of it were base point free, then it would define a morphism \( \psi : X \to \mathbb{P}^m \). Let \( \varphi : X \to \text{Alb}_r \) be the Stein factorization of \( \psi \), i.e. \( \varphi \) is surjective with connected fibers. Two geometric points \( x \) and \( x' \) of \( X \) have the same image under \( \varphi \), if and only if \( x \sim_{L_r} x' \). By Theorem 4.8, the map \( \varphi \) would meet the requirements of a generalized Albanese variety. Indeed, a curve \( Y \xhookrightarrow{\iota} X \) would be contracted by \( \varphi \), if \( \deg Y(\iota^* L_r) = 0 \). This means (by Theorem 4.8) that all families of semistable rank \( r \) vector bundles on \( X \) with trivial Chern classes become constant when restricted to \( Y \), or only finitely many representation classes modulo conjugation of \( \pi_1(Y) \) in \( U(r) \) are induced by representations of \( \pi_1(X) \).

If no line bundle \( L_r \) with \( L_r \sim L_r \) is base point free (note that \( L^{\otimes k} \sim L_r \), for all \( k > 0 \)), then Tsuji’s nef reduction theorem provides us with a rational version of the generalized Albanese variety up to birational equivalence. In this case we obtain only a birational model of the Albanese morphism and variety.

**Theorem 5.2** (see [BCE02, Theorem 2.1], see also [Tsu00]). There exists a dominant rational map \( X \xrightarrow{\text{alb}_r} \text{Alb}_r(X) \) with connected fibers such that:

(i) the line bundle \( L_r \) is numerically trivial on all compact fibers \( F \) of \( \text{alb}_r \) of dimension \( \dim(X) - \dim(\text{Alb}_r(X)) \);

(ii) for every general point \( x \in X \) and every irreducible curve \( C \) passing through \( x \) with \( \dim(\text{alb}_r(C)) > 0 \), we have \( C.L_r > 0 \);

(iii) there exist compact fibers of \( \text{alb}_r \).

Furthermore, the pair \((\text{alb}_r, \text{Alb}_r(X))\) is uniquely determined up to birational equivalence.

5.3 The chain of generalized Albanese morphisms. Even though we end up with an infinite sequence of rational morphisms \( X \xrightarrow{\text{alb}_r} \text{Alb}_r(X) \), for each \( r \in \mathbb{N} \), there are at most \( \rho(X) + 1 \) different generalized Albanese morphisms, since for almost all \( r \in \mathbb{N} \), we have \( L_r \sim L_{r+1} \). Since \( L_r \leq L_{r+1} \), we get a rational morphism \( \text{Alb}_{r+1}(X) \to \text{Alb}_r(X) \). So, we end up with the following commutative diagram.

\[
\begin{array}{cccccc}
\text{Alb}_{\infty}(X) & \xleftarrow{\text{alb}_{\infty}} & \cdots & \cdots & \cdots & \cdots \\
| & \downarrow & | & \downarrow & | & \downarrow \\
\text{Alb}_{r+1}(X) & \xrightarrow{\text{alb}_r} & \text{Alb}_r(X) & \xrightarrow{\text{alb}_r} & \cdots & \cdots \\
| & \downarrow & | & \downarrow & | & \downarrow \\
\text{Alb}_r(X) & \to & \cdots & \cdots & \cdots & \cdots \\
| & \downarrow & | & \downarrow & | & \downarrow \\
\psi & \to & X' & \to & \cdots & \cdots \\
| & \downarrow & | & \downarrow & | & \downarrow \\
\text{alb}_r & \to & \text{alb}_r & \to & \cdots & \cdots \\
\end{array}
\]

**Proposition 5.4** (Functoriality). If \( \psi : X \to X' \) is a morphism of projective varieties, then we have \( \psi^* L_r' \leq L_r \) for all \( r \in \mathbb{N} \cup \{ \infty \} \). Therefore, we have the following commutative diagram.

\[
\begin{array}{cccccc}
X & \xrightarrow{\psi} & X' \\
| & \downarrow & | & \downarrow & | & \downarrow \\
\text{alb}_r & \to & \text{alb}_r & \to & \cdots & \cdots \\
\end{array}
\]

**Proof.** Suppose that \( \iota : Y \to X \) is a morphism from a smooth curve to \( X \) with \( \deg(\iota^* \psi^* L_r') > 0 \). This implies by Theorem 4.3 that there exists a family \( \mathcal{E}' \) of rank \( r \) vector bundles with trivial Chern classes on \( X' \) parametrized by a connected scheme \( Z \) such that the pull back \( (\text{id}_Z \times (\psi \circ \iota))^* \mathcal{E}' \) of \( \mathcal{E}' \) to \( Z \times Y \) parametrizes different \( S \)-equivalence classes on \( Y \). However, then the family \( \mathcal{E} = (\text{id}_Z \times \psi)^* \) also parametrizes rank \( r \) vector bundles on \( X \) which pull back to non-\( S \)-equivalent classes. Consequently, again by Theorem 4.3, \( \deg(\iota^* L_r) > 0 \). \( \square \)
Theorem 6.2. Let \((X,H)\) be a polarized projective surface. Then there exists a surjective morphism \(\text{alb}_r : X \to \text{Alb}_r(X)\) with connected fibers, and an effective divisor \(D\) on \(X\), such that for all morphisms \(\iota : C \to X\) of irreducible curves with \(\iota(C) \not\subseteq D\) the following conditions are equivalent:

(i) \(\text{alb}_r(\iota(C))\) is a point;

(ii) the associated morphism \(\text{Hom}(\pi_1(X), U(r)) \rightarrow \text{Hom}(\pi_1(C), U(r))\) modulo conjugation has a finite image;

(iii) for any base scheme \(S\) and any rank \(r\) vector bundle \(E\) on \(X \times S\) such that, for each \(s\), \(E_s\) is semistable with numerically trivial Chern classes, the pull back of \(E\) to \(C \times S\) is a family of \(S\)-equivalent vector bundles.

The divisor \(D\) of exceptions can be written in the form \(D = C_1 + C_2 + \cdots + C_l\), where the \(C_i\) are irreducible and form a basis of a proper subspace of the rational Néron–Severi vector space \(\text{NS}(X) \otimes \mathbb{Q}\). In particular, we have \(l < \dim_{\mathbb{Q}}(\text{NS}(X) \otimes \mathbb{Q})\).

6.3 Preparations for the proof. We consider the nef line bundle \(\mathcal{L}_r\) on \(X\) satisfying the equivalence of Theorem 4.3. There are two extreme cases where the proof is a simple remark. When \(C.\mathcal{L}_r > 0\), for all curves \(C\), then we set \(\text{alb}_r\) to be the identity morphism of \(X\). If \(C.\mathcal{L}_r = 0\) for all curves, then we set \(\text{Alb}_r(X) = \text{Spec}(\mathbb{C})\), and we are finished.

Thus, we assume from now on that \(\mathcal{L}_r\) is a numerically non-trivial nef line bundle vanishing on a non-empty set \(\{C_i\}_{i \in I}\) of irreducible curves. It follows from the construction that all the curves \(C_i\) in this family are contracted to points by the classical Albanese morphism.

Being a nef divisor, \(\mathcal{L}_r\) is the limit of ample divisors (with rational coefficients), which yields \(\mathcal{L}_r^2 \geq 0\). This implies the following lemma.

Lemma 6.4. If \(C \subset X\) is an effective divisor with \(C^2 > 0\), then \(C.\mathcal{L}_r > 0\).
6.5 The nef reduction for $\text{Alb}_1(X) = \text{Spec}(\mathbb{C})$. We consider the curves $\{C_i\}_{i \in I}$ as vectors in the rational Nerón–Severi space $\text{NS}_Q(X)$. The dimension of this vector space is the Picard number $\rho(X)$ of $X$. The points $\{C_i\}_{i \in I}$ lie on the hyperplane $\{C \in \text{NS}_Q(X) \mid C.L_r = 0\}$. Suppose that there is a non-trivial linear relation among the $C_i$. If the number of these curves exceeds $\rho(X) - 1$, then we have at least one such relation. We write the linear relation $a_1C_1 + \cdots + a_mC_m = a_{m+1}C_{m+1} + \cdots + a_MC_M$ with positive rational $a_i$, and $C_i$ different from $C_j$ whenever $i \neq j$.

After multiplication with a positive integer, we may assume the $a_i$ to be integers. We set $D_1 := a_1C_1 + \cdots + a_mC_m$ and $D_2 := a_{m+1}C_{m+1} + \cdots + a_MC_M$. Since $D_1$ and $D_2$ coincide in $\text{NS}_Q(X)$, their difference is torsion in the Nerón–Severi group. So again, after multiplying with an integer, we may assume that the effective Cartier divisor classes $D_1$ and $D_2$ coincide. (Here we use the fact that the Picard torus, the dual of the Albanese torus, is trivial.)

Because $D_1$ and $D_2$ have no common components, $D_1^2 = D_1D_2 \geq 0$. In view of Lemma 6.4, and $D_1.L_r = 0$, we conclude that $D_1^2 = 0$. This implies that $D_1$ and $D_2$ are disjoint.

Consequently, the line bundle $L := \mathcal{O}_X(D_1) \cong \mathcal{O}_X(D_2)$ has two linearly independent sections which do not intersect. Thus, $L$ is base point free and defines a morphism whose Stein factorization we denote by $\text{alb}_r : X \to \text{Alb}_r(X)$.

On the one hand, we have that $F.L_r = 0$ for all fibers of $\text{alb}_r$. On the other hand, suppose $C.L_r = 0$ for a curve $C \subset X$. Let $F$ be an irreducible fiber of $\text{alb}_r(X)$. If $C$ were not contained in a fiber, then we would have $(C + mF)^2 > 0$ for $m \gg 0$. However, we have $(C + mF).L_r = 0$, which contradicts Lemma 6.4. Thus, each curve $C$ with $C.L_r = 0$ is contained in a fiber.

This means that the effective divisor $D$ of Theorem 6.2 can be taken to be the empty set once we have a linear relation between the $\{C_i\}_{i \in I}$ in $\text{NS}_Q(X)$. Since the resulting morphism $\text{alb}_r$ contracts all these curves, we conclude that $\text{alb}_r$ does not depend on the chosen linear relation.

6.6 The nef reduction when $\text{Alb}_1(X)$ is a curve. We consider the morphism $\text{alb}_1 : X \to \text{Alb}_1(X)$. This morphism is the Stein factorization of the classical Albanese morphism. It follows from $L_1 \leq L_r$ that each curve $C$ with $C.L_r = 0$ is contained in a fiber of this morphism. Let $F$ be the generic fiber of $\text{alb}_1$.

If $F.L_r = 0$, then all curves $C$ with $C.L_r = 0$ are contracted by $\text{alb}_1$. Consequently we set $\text{alb}_r = \text{alb}_1$ and Theorem 6.2 is proven.

We suppose now that $F.L_r$ is positive. The set of curves $\{C_i\}_{i \in I}$ consists of components of reducible fibers of the morphism $\text{alb}_1$. We will show that this set is not only finite but linearly independent in $\text{NS}_Q(X)$. Indeed, if there were a linear relation, then we would obtain (see §6.5) an effective divisor $D_r = a_1C_1 + \cdots + a_mC_m$. This divisor satisfies $D_r^2 = 0$, $D_r.L_r = 0$, and consists of fiber components. This contradicts Zariski’s lemma (see [BPV84, Lemma III.8.2]), because $F.L_r > 0$ for all fibers $F$. This shows that Theorem 6.2 holds when setting $\text{alb}_r = \text{id}_X$.

6.7 Remark. The finite collection of curves $\{C_i\}_{i \in I}$ must have a negative definite intersection matrix, because of Zariski’s lemma. Thus, by Grauert’s criterion (see [BPV84, Theorem III.2.1]), there exists a contraction of these curves. However, this contraction is not necessarily a projective morphism. If it were, we could take this contraction to be our generalized Albanese morphism $\text{alb}_r$. 

731
6.8 The nef reduction for dim(Alb$_1$(X)) = 2. In this case, the generalized Albanese morphism alb$_1: X \to$ Alb$_1(X)$ contracts finitely many curves. Among those curves are the $\{C_i\}_{i \in I}$ which are numerically trivial with respect to $L_r$. The intersection matrix of these $\{C_i\}_{i \in I}$ is negative definite. This yields that these curves form a basis of a proper subspace of NS$_Q(X)$. Again, just setting alb$_r = $ id$_X$, the assertions of Theorem 6.2 are fulfilled. As before, §6.7 applies.

6.9 Surfaces of Kodaira dimension less than 2. Let $X$ be a projective algebraic surface of Kodaira dimension $\kappa(X) \leq 1$. We assume that $X$ is minimal. This is not a restriction, because the fundamental group of rational curves is zero. Table 1 gives the generalized Albanese morphism for these surfaces following the Enriques–Kodaira classification (see [BPV84, VI]). The sixth and seventh rows are perhaps the most interesting ones. They show that the generalized Albanese morphisms may reveal more of the surface than the classical one. We assume in these two rows that the surface $X$ is not a product of two curves.

6.10 A class of examples. Let $G$ be a finite group with $|G|$ elements and $C_1$, $C_2$ be two smooth projective curves with a $G$ action such that:

(a) the genera $g_{C_1}$ and $g_{C_2}$ are positive;
(b) $G$ acts free on $C_1$, i.e. the quotient map $C_1 \to C_1/G$ is étale;
(c) there are no $G$-invariant global sections in $H^0(C_2, \omega_{C_2})$, which is equivalent to $C_2/G \cong \mathbb{P}^1$.

We obtain a free $G$-action on $C_1 \times C_2$. Let $X := (C_1 \times C_2)/G$ be the quotient of this action and $p : C_1 \times C_2 \to X$ the projection. Since $C_1 \times C_2$ is embedded into its Albanese variety, we deduce from Proposition 5.5 that $L_{|G|}^r C > 0$ for all curves $C \subset X$. Thus, alb$_r = $ id$_X : X \to X$ for all $r \geq |G|$, whereas the classical Albanese morphism is just the map to the curve $C_1/G$.
