Introduction: The application of recovery principles within everyday mental health services is understudied.

Objectives and aims: We studied the implementation of a programme of intensive case management (ICM) emphasizing recovery principles in an Irish community mental health service.

Methods: Eighty service attenders with severe and enduring illness were randomized into groups (1) receiving a programme of ICM, (2) receiving treatment as usual (TAU). Groups were compared before/after the programme for general psychopathology using the Brief psychiatric Rating Scale [BPRS] (clinician rated) and How are You? Scale (self-rated). The Functional Analysis of Care Environments [FACE] scale provided assessment of functional domains.

Results: The overall group [mean age 44.5±13.2 years; 60% male] had mean total Health of the Nation Outcome Scale [HoNOS] scale scores 10.5±4.6 with impaired social functioning especially prominent (mean social subscale score 5.0±2.7). The ICM group were younger (p< 0.01) with higher baseline scores on the HoNOS social subscale and BPRS (p< 0.05). An analysis of covariance, controlling for these baseline differences, indicated greater improvement in BPRS scores (p=0.001), How are You? scores (p=0.02) and FACE domains for cognition, symptoms and interpersonal relationships (all p< 0.001) in the ICM group. The ICM group underwent greater changes in structured daily activities that were linked to improved BPRS scores (p=0.01).

Conclusions: A programme of ICM emphasizing recovery principles allowed significant improvement across psychopathological and functional domains. Improvements were linked to enhanced engagement with structured daily activities. Recovery-oriented practices can be integrated into existing mental health services and provided alongside traditional models of care.
