(Received 2 February 2007 – Revised 19 June 2007 – Accepted 20 June 2007)

Recent data reported that inulin-type fructans extracted from chicory roots regulate appetite and lipid/glucose metabolism, namely, by promoting glucagon-like peptide-1 (GLP-1) production in the colon. The Agave genus growing in different regions of Mexico also contains important amounts of original fructans, with interesting nutritional and technological properties, but only few data report their physiological effect when added in the diet. Therefore, we decided to evaluate in parallel the effect of supplementation with 10% agave or chicory fructans on glucose and lipid metabolism in mice. Male C57Bl/6J mice were fed a standard (STD) diet or diet supplemented with Raftilose P95 (RAF), fructans from Agave tequilana Gto. (TEQ) or fructans from Dasylirion spp. (DAS) for 5 weeks. The body weight gain and food intake in mice fed fructans-containing diets were significantly lower than the ones of mice fed the STD diet, TEQ leading to the lowest value. Serum glucose and cholesterol were similarly lower in all fructans-fed groups than in the STD group and correlated to body weight gain. Only RAF led to a significant decrease in serum TAG. As previously shown for RAF, the supplementation with agave fructans (TEQ and DAS) induced a higher concentration of GLP-1 and its precursor, proglucagon mRNA, in the different colonic segments, thus suggesting that fermentable fructans from different botanical origin and chemical structure are able to promote the production of satietogenic/incretin peptides in the lower part of the gut, with promising effects on glucose metabolism, body weight and fat mass development.

Type 2 diabetes is a critical disease clearly linked to obesity and physical inactivity. Appropriate nutritional advice is an important way to control and manage all the metabolic disorders associated with excessive fat storage. It has been proposed that some carbohydrates, which are fermented in the caeco-colon, might be of particular interest in the field of obesity. Fructans are non-digestible and fermentable carbohydrates, which have interesting metabolic effects (decrease in fat mass development, steatosis and glycaemia), by acting through a mechanism different from the common dietary fibres prone to act on lipid metabolism, since they exhibit no gel-forming properties. Interestingly, the fermentation of fructans in the colon promotes incretin production. Glucagon-like peptide (GLP)-1 is an incretin secreted by endocrine L cells after post-translational modification of the peptide derived from proglucagon gene expression; it is an important regulator of the pancreatic β-cell, known to promote insulin secretion, proinsulin biosynthesis and islet cell growth and neogenesis. Moreover, it is also considered as a key satietogenic peptide. We have previously shown that Raftilose (RAF), a short-chain fructan derived from chicory roots inulin, increased portal and colonic GLP-1 (7-36) amide levels and that mice lacking GLP1 receptor functionality did not respond to RAF in terms of regulation of food intake, glycaemia and fat mass development.

On the other hand, López et al. determined the molecular structure of fructans from Agave tequilana Weber var. azul, using different techniques. These fructans consist of a complex mixture containing principally β(2-1) linkages, but also some β(2-6), with branches, and with terminal or internal glucose. Mancilla-Margalli & López reported the structural differences among agave fructans as well as within the same Agave species but grown in different environmental regions. The observed structural heterogeneity could be attributed to the plant adaptation mechanisms to survive in very inhospitable areas. These authors classified agave fructans in three major groups with two different structures, graminans and agavins. No physiological effect of agave-derived fructans has been reported until now. Gibson & Wang evaluated the properties of different types of fructo-oligosaccharides and

Agave fructans in obese mice 255

found a variable growth of each of the different bacterial species – responsible for a specific fermentation pattern – which was dependent on the type of oligosaccharide used\textsuperscript{10}. Interestingly an \textit{in vitro} assessed the prebiotic effect of fructans and proved an efficient stimulation of growth of Bifidobacteria and Lactobacilli by several agave fructans – \textit{Dasylirion} spp. (DAS) and \textit{A. tequilana} Gto (TEQ)\textsuperscript{11}. This tremendous prebiotic potential opens new and excited alternatives for agave fructans as food ingredients and/or health-promoting ingredients.

Cani \textit{et al.} compared the effect of the degree of polymerization (DP) of three fructans derived from inulin on GLP-1 (7-36) amide synthesis and showed that the most important increase was observed with short-chain fructans used in the present study, which is mostly fermented in the upper part of the caecum colon\textsuperscript{12}. As mentioned previously, fructans from TEQ and DAS exhibit a similar bifidogenic potential \textit{in vitro} as compared with Raftilose\textsuperscript{8}Synergy1; the profile of fermentation and the extent of bacterial growth were dependent on the bacterial strain and on the Agave species or fructan type\textsuperscript{11}. Matrix assistant laser desorption/ionization–time of flight (MALDI-TOF)-MS analysis (data not shown) of fructans from TEQ revealed the presence of a larger proportion of low DP fructo-oligosaccharides than in DAS, thus suggesting an effect prone to occur mostly in the caecum and in the proximal colon. DAS would be expected to be fermented mostly in the medial and distal colon. The difference in behaviour of TEQ and DAS compared with RAF, which is linear, could be attributed to the structure of this kind of fructans assuming similarity with that previously reported by Lopez \textit{et al.} for \textit{A. tequilana} Weber var. azul, which present linkages of the type \(\beta(2-1)\) principally, but also some \(\beta(2-6)\) and branched of the neo type\textsuperscript{8}.

Therefore, due to fructans structural diversity and their putative benefits on health, the aim of the present work was to evaluate the potential of TEQ v. inulin type fructans to modulate glucose and lipid metabolism and GLP-1 secretion in mice. In this work, DAS was included, which possesses similar characteristics with agave, such as plant morphology, geographical distribution and pollen characteristics. Fructans-like storage of carbohydrate has been found in this plant, in addition to its prebiotic properties.

Materials and methods

\textbf{Animals and diets}

Thirty-two male C57Bl/6J mice from Charles River Laboratories (12 weeks old at the beginning of the experiment) were housed in a temperature- and humidity-controlled room with a 12 h light–dark cycle. They were divided into four groups (eight mice per group, four mice per cage) according to diet. After an acclimatization period of 6 d before the experiment, control (standard (STD) diet) mice were fed pelleted A04 standard diet (UAR, Villemoisson-sur-Orge, France) whereas RAF-, TEQ- and DAS-diet mice received a diet prepared by mixing 90 g A04 standard diet with 10 g corresponding fructan (RAF P95, TEQ and DAS respectively). The A04 standard diet contained the following (g/100 g dry diet): protein 19.3 (consisting of equivalent mix of soyabean and fish proteins); total carbohydrates obtained from maize,
blood samples after an extraction with chloroform-methanol according to Folch et al.13. Protein concentration was measured by the method of Bradford using bovin serum albumin as standard14. Haematoxylin/eosin and oil red staining were performed on liver tissue cryostat sections.

**Isolation of total RNA**

Total RNA was isolated from each intestinal segment using the TriPure Isolation Reagent (Roche, Indianapolis, IN, USA). Approximately 50–100 mg intestinal tissue was used to extract total RNA. The quantity and the purity of RNA were determined by UV spectrophotometry at 260 nm and 280 nm.

**Proglucagon and β-actin mRNA by RT-PCR**

RT-PCR was performed with an input of 1 µg RNA using the kit for RT-PCR (Access RT-PCR system; Promega Corporation, Madison, WI, USA). Primers of interest for the amplification of cDNA were for the sequences of the sense and antisense primers respectively: 5’-GTAATGCTGGTACAAGGCAG-3’ and 5’-TTGATGAAGTCTCTGGTGGCA-3’ for proglucagon gene, and 5’-CTGACCGAGCGTGAGCT ACAG-3’ and 5’-GGTGCTAGGAGCCAGGGCAG-3’ for β-actin gene. Twenty-three cycles were performed for the detection of β-actin transcripts. Control tubes without RNA templates were used to check contamination. RT-PCR products (3 µl from each) were resolved in an 18 g/l agarose gel in TAE buffer and visualized by ethidium bromide UV-light staining.

**Intestinal glucagon-like peptide-1 (7-36) amide extraction**

Extraction of GLP-1 (7-36) amide from intestinal segments (caecum and colon) was carried out with an ethanol-acid solution (10 ml/g tissue). Samples were homogenized at maximum speed and placed at 4°C for 24 h. The homogenate was centrifuged (2000 g) and the supernatant fraction was decanted and diluted 100- and 250-fold in saline solution (9 g NaCl/l) for caecum and colon, respectively. Concentrations of intestinal GLP-1 (7-36) amide were measured as previously described for blood samples.

**Statistical analysis**

Results are expressed as mean values with their standard errors of the mean. Statistical differences between groups were evaluated using one-way ANOVA followed by a Bonferroni or least squares difference or Tukey post hoc test using SPSS 11.0 for Windows (SPSS, Chicago, IL, USA). For portal vein GLP-1, the analysis was done with logarithmic values. Differences were considered significant at P≤0.05. Correlations between parameters were assessed by Pearson’s correlation test, using GraphPad Prism version 4.00 for Windows (GraphPad Software, San Diego, CA, USA; www.graphpad.com). P < 0.05 was regarded as statistically significant.

**Results**

**Food intake, body weight and faeces**

In general, fructan supplementation decreased daily food and/or energy intake (Table 1) and increased faeces excretion (Table 1) compared with the STD diet. Concerning food intake (Table 1), the mice with diet supplemented with RAF and TEQ ate 11 % and 10 % less food than STD, respectively. Total energy intake (Fig. 2) was significantly lower in all fructan-fed groups than in the STD group. Mice receiving TEQ, DAS and RAF diets had a significantly lower body weight gain throughout the treatment (Fig. 1). Only the TEQ diet significantly increased total faeces excretion compared with the STD group (17 % more on dry basis), the increase being non-significant in the other groups, namely, RAF and DAS (Table 1).

**Liver and epididymal tissue weight and lipid contents**

Only the TEQ diet significantly decreased both liver and adipose tissue weights as compared with STD. The sole biochemical modification observed in this group was a decrease in hepatic cholesterol level.

*a,b Mean values with unlike superscript letters were significantly different (P<0.05). n=11 for food intake; n=4 for faeces. Liver weight: n=7 for MAD, TEQ; n=8 for MAD and DAS. Epithymal tissue: n=7 for MAD and TEQ; n=8 for MAD and DAS, n=8 for liver TAG, cholesterol and NEFA.

*For details of diets and procedures, see Materials and methods.
fructans had a pronounced effect on total caecum weight (Fig. 4): significant enlargement of the caecum was observed in mice fed the TEQ diet (almost doubled as compared with the STD diet); the DAS and RAF diets increased total caecum weight by about 65 %. A coordinate and significant increase in the caecum wall weight occurred, this parameter being increased by 77 %, 64 % and 43 % for TEQ, RAF and DAS diets, respectively, compared with the STD diet.

Figure 2. Food intake of mice fed a standard diet (STD) or a diet supplemented with Raftilose P95 (RAF), Agave tequilana Gto. (TEQ) or Dasylirion spp. (DAS). Mean values (n 11) with their standard errors of the mean. Mean values with different letters were significantly different (P≤0·05). For details of diets and procedures, see Materials and methods.

Histological analysis

The histological analysis of the liver did not reveal any differences between groups. A normal structure of the hepatocytes arranged in typical centriportal trabeculi characterized all groups. Fat stained with oil red led to a negative reaction.

Fructans had a pronounced effect on total caecum weight (Fig. 1). The caecum weight of mice receiving DAS, TEQ and RAF diets was greater than in the STD diet; the DAS and RAF diets increased total caecum weight by about 65 %. A coordinate and significant increase in the caecum wall weight occurred, this parameter reaching about 20 % in animals receiving DAS, TEQ and RAF diets, respectively. Reduction of cholesterol concentrations by 31 %, 11 % and 7 % in mice fed RAF, TEQ and DAS diets, respectively (Table 2). TAG concentrations were significantly lowered by 19, 15 and 14 % – as compared with the fructan diet and in the distal colon for the RAF diet. When measured in the portal vein (Fig. 6), GLP-1 concentrations in mice fed fructan diets were significantly higher in all fructans diets than in the STD diet; it was almost doubled in the RAF group v. control.

Discussion

The supplementation of diet with soluble fibres has been reported to have beneficial effects in patients with type 2 diabetes mellitus: it helps to improve glycaemic control, decreases hyperinsulinaemia and lowers plasma lipid concentrations. However, the mechanisms by which fibre may exert some of those effects are not completely understood. The viscosity of the fibre has been proposed as an important property. However, some fibres, such as non-digestible oligosaccharides, may have effects despite the fact that they have no gelling properties and do not modify viscosity. Fructan fermentation, leading to the production of SCFA, which have no gelling properties and do not modify viscosity, may have effects despite the fact that they have no gelling properties and do not modify viscosity. Fructan fermentation, leading to the production of SCFA, may have effects despite the fact that they have no gelling properties and do not modify viscosity.
production agrees with other studies after fructan consumption by rats and hamsters. The effect on the increase in caecum tissue reflects hypertrophy and suggests increased bacterial activity, namely, an increase in SCFA production through fermentation by colonic bacteria.

Some positive effects similar to the ones already described for inulin-type fructans were demonstrated, namely, a decrease in energy intake and body weight gain, together with a decrease in glycaemia and triacylglycerolaemia. Fasting triacylglycerolaemia has been considered as a factor involved in dietary obesity in rodents. However, taking into account the data obtained from animals of all groups, there was no significant correlation between body weight gain and triacylglycerolaemia (Pearson’s test *P* > 0.05), contrary to what was shown in animals fed with soya isoflavone. Therefore, it is improbable that the sole decrease in energy intake could be responsible for the improvement of triacylglycerolaemia in fructans-fed animals. However, a positive correlation exists between blood glucose or cholesterol and body weight gain in the present study, thus suggesting that those parameters are more related to energy intake and fat mass development.

*A. tequilana* was the most efficient to decrease body weight gain, whereas its effect on glycaemia and on triacylglycerolaemia was less pronounced than the one shown for RAF. This suggests that the decrease in body weight is not the sole way by which the dietary fructans tested in this study may modulate lipid and glucose homeostasis. Delzenne & Kok mentioned that the main systemic effect of RAF feeding in rats is a decrease in serum TAG. Kok et al. reported that RAF intake reduces postprandial glycaemia and insulinaemia by 17 and 26%, respectively, and this could be implicated in lower lipogenesis and thus in lower hepatic TAG production. Here, we confirm the decrease in plasma TAG levels upon RAF feeding.}

in triacylglycerolaemia due to RAF; whereas agave fructans had no effect on this parameter. However, all types of fructans significantly decreased glycaemia. This would suggest that a decrease in triacylglycerolaemia due to fermentable fibres is not necessarily attributable to a decrease in glucose availability.

Gut fermentation has to be taken into account in the interpretation of the metabolic effects of dietary fructans. The fermentation of fructans in the caeco-colon leads to the production of SCFA, propionate being an inhibitor of hepatic lipid synthesis.

Propionate, which is largely produced through the fermentation of all tested fructans, has been shown to decrease cholesterol synthesis in different models. Interestingly, we observed a significant decrease in serum cholesterol level, with a significant decrease in liver cholesterol for TEQ treatment only.

The trend of the effects on food/growing behaviour was similar with agave fructans and with RAF. The effect of fructans on energy intake is not due to any ‘direct’ effect of those fructans, but is really attributable to a metabolic effect in the caeco-colon, due to fermentation. Fermentation is a key point, since, in obese Zucker rats, the administration of non-fermentable cellulose in place of oligofructose does not allow the improvement of any parameters linked to fat mass, body weight or lipid metabolism.

Moreover, and to support the lack of ‘direct effect’ due to the treatment with fructans, mice lacking the GLP-1 receptor (KO mice or mice treated chronically with GLP-1 receptor antagonist) and treated with inulin-type fructans do not exhibit any effect on satiety, body weight and fat mass as compared with mice receiving the basal corresponding diet, thus showing that the effect of fructans on satiety (and consequences on body weight) are well due to the interaction with GLP-1 production, and might not occur through fructans per se.

GLP-1 could play a role in the modulation of food intake and glycaemia, since all types of fructans increased its concentration in the portal vein. An increase in GLP-1 caecal content, and of its mRNA precursor (proglucagon) in different colon sections, are in accordance with the hypothesis that the higher GLP-1 secretion in the portal vein comes from a fermentation-dependent increase in proglucagon expression in L cells, which are present all along the lower part of the gut. Moreover, recent data suggest that RAF may increase GLP-1 colonic content by promoting L cell differentiation. SCFA, which are produced in the gut by

Fructan fermentation, have been reported to stimulate secretion of proglucagon-derived peptides, butyrate being the main acid implicated\(^{2,45}\). Recently, Zhou et al., by means of in vitro analysis, found that butyrate increased proglucagon gene expression in a dose-dependent manner\(^{44}\). In the present study, we have observed that the increase in the proglucagon mRNA level and GLP-1 in the different intestinal segments was different depending on the fructan source evaluated.

Interestingly, among tested fructans, the one from \textit{A. tequilana} was the most potent to decrease fat mass, body and liver weight. We propose that this novel source of fructans could be interesting in studies devoted to relate specific modulation of the microbial flora and the risk of diseases associated with obesity.

Are those studies relevant to human health and behaviour? Flint et al. examined the effect of intravenously infused GLP-1 on subjective appetite sensations after an energy-fixed breakfast and on spontaneous energy intake at an \textit{ad libitum} lunch\(^{45}\). They reported that GLP-1 enhanced satiety and reduced energy intake and thus may play a physiological regulatory role in controlling appetite and energy intake in human subjects. Piche et al. have shown that dietary fructans were able to increase GLP-1 production several hours after ingestion\(^{46}\); on the other hand, we have recently shown that dietary RAF was able to induce satiety in normal human volunteers\(^{47}\). The door is open to start studies with other types of fructans, from different botanical and geographical origin. Finally, the findings of the present study emphasize the potential of improving glucose and lipid homeostasis as well as the modulation of GLP-1 and proglucagon expression by RAF and fructans from \textit{A. tequilana} and \textit{Dasylirion} spp. In addition, the present results show a positive influence of the fructans on body weight control, which might be of interest in the control of obesity.
