Pseudoprime Reductions of Elliptic Curves

C. David and J. Wu

Abstract. Let $E$ be an elliptic curve over $\mathbb{Q}$ without complex multiplication, and for each prime $p$ of good reduction, let $n_E(p) = |E(F_p)|$. For any integer $b$, we consider elliptic pseudoprimes to the base $b$. More precisely, let $Q_{E,b}(x)$ be the number of primes $p \leq x$ such that $b^{n_E(p)} \equiv b \pmod{n_E(p)}$, and let $\pi_{E,b}^{\text{pseu}}(x)$ be the number of compositive $n_E(p)$ such that $b^{n_E(p)} \equiv b \pmod{n_E(p)}$ (also called elliptic curve pseudoprimes). Motivated by cryptography applications, we address the problem of finding upper bounds for $Q_{E,b}(x)$ and $\pi_{E,b}^{\text{pseu}}(x)$, generalising some of the literature for the classical pseudoprimes to this new setting.

1 Introduction

The study of the structure and size of the group of points of elliptic curves over finite fields has received much attention since Koblitz and Miller in 1985 independently proposed elliptic curve cryptography, an approach to public-key cryptography based on the algebraic structure of elliptic curves over finite fields. Those cryptosystems guarantee, in general, a high level of security with less cost in the size of the keys, whenever the order of the group has a big prime divisor.

Let $E$ be an elliptic curve defined over $\mathbb{Q}$ with conductor $N_E$ and without complex multiplication (CM), and denote by $E(F_p)$ the reduction of $E$ modulo $p$. Writing $n_E(p) := |E(F_p)|$, it is an interesting problem to study the asymptotic behavior of

$$\pi_E^{\text{twin}}(x) := \left| \{ p \leq x : n_E(p) \text{ is prime} \} \right|.$$ 

Here and in the sequel, the letters $p$, $q$, and $\ell$ denote prime numbers. Koblitz [11] conjectured that as $x \to \infty$,

$$\pi_E^{\text{twin}}(x) \sim \frac{C_E^{\text{twin}} x}{(\log x)^2},$$

with an explicit constant $C_E^{\text{twin}}$ depending only on $E$ (see [5] (2.5) for its precise definition). It is easy to see that if $C_E^{\text{twin}} = 0$, then $\pi_E^{\text{twin}}(x) \ll 1$ for all $x \geq 1$. The asymptotic formula (1.1) can be regarded as the analogue of the twin prime conjecture for elliptic curves. As in the classical case, Koblitz’s conjecture is still open, but was shown to be true on average over all elliptic curves [11]. One can also apply

AMS subject classification: 11N36, 14H52.

Keywords: Rosser-Iwaniec sieve, group order of elliptic curves over finite fields, pseudoprimes.
sieve methods to get unconditional or conditional upper bounds for $\pi_{\text{twin}}^{E}(x)$. The best unconditional upper bound is due to Zywina [22, Theorem 1.3], and the best bound under the Generalized Riemann Hypothesis (GRH) is due to David and Wu [5, Theorem 2]. For $E$ an elliptic curve over $\mathbb{Q}$ without CM, and for any $\varepsilon > 0$, those bounds are

$$\pi_{E}^{\text{twin}}(x) \leq \begin{cases} (24c_{E}^{\text{twin}} + \varepsilon) \frac{x}{(\log x) \log_{2} x} & \text{(unconditionally),} \\ (10c_{E}^{\text{twin}} + \varepsilon) \frac{x}{(\log x)^{2}} & \text{(under the GRH),} \end{cases}$$

where $\log_{k}$ denotes the $k$-fold logarithm function.

Let $b \geq 2$ be an integer. We say that a composite positive integer $n$ is a pseudo-prime to base $b$ if the congruence

$$b^{n} \equiv b \pmod{n}$$

holds. In practice, primality-testing algorithms are not fast when one wants to test many numbers in a short amount of time, and pseudoprime testing can provide a quick pre-selection procedure to get rid of most of the pretenders. The distribution of pseudoprimes was studied by many authors including [6, 17]. Motivated by applications in cryptography, the question of the distribution of pseudoprimes in certain sequences of positive integers has received some interest (see [3, 7, 14, 15, 18]). In particular Cojocaru, Luca, and Shparlinski [3] have investigated distribution of pseudoprimes in $\{n^{E}(p)\}_{p \text{ primes}}$. Define

$$Q_{E,b}(x) := \left| \left\{ p \leq x : b^{n_{E}(p)} \equiv b \pmod{n_{E}(p)} \right\} \right| .$$

According to Fermat’s little theorem, if $n_{E}(p)$ is a prime such that $n_{E}(p) \nmid b$, then (1.3) holds with $n = n_{E}(p)$. Thus,

$$\pi_{E}^{\text{twin}}(x) \leq Q_{E,b}(x)$$

for all $x \geq 2$. Cojocaru, Luca, and Shparlinski [3, Theorems 1 and 2] proved that for any fixed base $b \geq 2$ and elliptic curve $E$ without CM, the estimates

$$Q_{E,b}(x) \ll_{E,b} \begin{cases} \frac{x(\log_{3} x)^{2}}{(\log x) \log_{2} x} & \text{(unconditionally),} \\ \frac{x(\log_{2} x)^{2}}{(\log x)^{2}} & \text{(under the GRH)} \end{cases}$$

hold for all $x \geq 10$, where the implied constant depends on $E$ and $b$.

The first aim of this paper is to improve (1.4). We noticed that there are two inaccuracies in Cojocaru, Luca, and Shparlinski’s proof of (1.4). With the notation of [3], we have $t_{b}(\ell) \mid (n_{E}(p) - 1)$ instead of $n_{E}(p)$ (see [3, page 519]). Thus the inequality $\#\mathcal{J} \leq \sum_{c \leq x} \Pi_{c}(n_{E}(p))$ does not hold (see [3, p. 520]). Secondly the statements of [3, Lemmas 3, 4, 6, and 7] are not true when $(m, M_{E}) \neq 1$ (see Section 2 for the definition of $M_{E}$). Then, the proofs of Lemma 9 and 10 hold only for $(m, M_{E}) = 1$. This is not sufficient for the proof bounding $\#\mathcal{J}$, since $t_{b}(\ell)$ is not necessarily coprime with $M_{E}$.
Theorem 1.1 Let $E$ be an elliptic curve over $\mathbb{Q}$ without CM and let $b \geq 2$ be an integer. For any $\varepsilon > 0$, we have

$$Q_{E,b}(x) \leq \begin{cases} (48e^\gamma + \varepsilon) \frac{x \log_3 x}{(\log x) \log_2 x} & \text{ (unconditionally),} \\ (28e^\gamma + \varepsilon) \frac{x \log_2 x}{(\log x)^2} & \text{ (under the GRH)} \end{cases}$$

for all $x \geq x_0(E, b, \varepsilon)$, where $\gamma$ is the Euler constant.

Denoting by $\pi(x)$ the number of primes not exceeding $x$, and by $\pi_{b}^{\text{pseu}}(x)$ the number of pseudoprimes to base $b$ not exceeding $x$, it is known that (see [6, 17])

(1.5) \hspace{1cm} \pi_{b}^{\text{pseu}}(x) = o(\pi(x))

as $x \to \infty$. Precisely, Pomerance [17, Theorem 2] proved that \footnote{In [17], the definition of pseudoprime to base $b$ is slightly stronger: $b^{n-1} \equiv 1 \pmod{n}$ in place of $b^n \equiv b \pmod{n}$. It is easy to adapt Pomerance’s proof of [17, Theorem 2] to obtain (1.6), as we do in this paper for the context of elliptic curves pseudoprimes. See Section 5 for more details.}

(1.6) \hspace{1cm} \pi_{b}^{\text{pseu}}(x) \leq \frac{x}{\sqrt{L(x)}}

for $x \geq x_0(b)$, where $L(x) := e^{(\log x)(\log, x)/\log, x}$. As an analogue of $\pi_{b}^{\text{pseu}}(x)$ for an elliptic curve, we introduce

$$\pi_{E,b}^{\text{pseu}}(x) := \left| \left\{ p \leq x : n_E(p) \text{ is pseudoprime to base } b \right\} \right|.$$ 

Clearly,

$$Q_{E,b}(x) = \pi_{E}^{\text{twin}}(x) + \pi_{E,b}^{\text{pseu}}(x).$$

In view of (1.5), it seems reasonable to conjecture

(1.7) \hspace{1cm} \pi_{E,b}^{\text{pseu}}(x) = o(\pi_{E}^{\text{twin}}(x))

as $x \to \infty$.

In order to establish an analogue of (1.6) for $\pi_{E,b}^{\text{pseu}}(x)$, we need a supplementary hypothesis.

Hypothesis 1.2 Let $E$ be an elliptic curve over $\mathbb{Q}$. There is a positive constant $\delta$ such that

(1.8) \hspace{1cm} M_E(n) := \#\{ p : n_E(p) = n \} \ll_{E} n^{\delta}

holds uniformly for $n \geq 1$, where the implied constant can depend on the elliptic curve $E$. 

https://doi.org/10.4153/CJM-2011-044-x Published online by Cambridge University Press
By the Hasse bound $|p + 1 - n_E(p)| \leq 2\sqrt{p}$, it is easy to see that

$$n_E(p)/16 \leq p \leq 16n_E(p)$$

for all $p$. Thus the relation $n_E(p) = n$ and the Hasse bound imply that $|p - n| \leq 9\sqrt{n}$. Therefore (1.8) holds trivially with $\delta = \frac{1}{2}$ and an absolute implicit constant. It is conjectured that (1.8) should hold for any $\delta > 0$ (see [12, Question 4.11]). Kowalski proved that this conjecture is true for elliptic curves with CM [12, Proposition 5.3] and on average for elliptic curves without CM [12, Lemma 4.10].

The next theorem shows that we can obtain a better conditional upper bound for $\pi_{E,p}\(x\)$ than $\pi_{E,\text{twin}}\(x\)$, which can be regarded as an analogue of (1.6) for elliptic curves without CM.

**Theorem 1.3** Let $E$ be an elliptic curve over $\mathbb{Q}$ without CM and $b \geq 2$ be an integer. If we assume the GRH and Hypothesis 1.2 with $\delta < \frac{1}{24}$, we have

$$\pi_{E,b}^\text{pseudo}(x) \leq \frac{x}{L(x)^{1/38}}$$

for all $x \geq x_0(E, b, \delta)$.

In view of Koblitz’s conjecture (1.1), the result of Theorem 1.3 then encourages our belief in conjecture (1.7).

By combining (1.10) and the second part of (1.2), we immediately get the following result.

**Corollary 1.4** Let $E$ be an elliptic curve over $\mathbb{Q}$ without CM and $b \geq 2$ be an integer. If we assume the GRH and hypothesis 1.2 with $\delta < \frac{1}{24}$, for any $\varepsilon > 0$ we have

$$Q_{E,b}(x) \leq (10G_E^\text{twin} + \varepsilon)\frac{x}{(\log x)^2}$$

for all $x \geq x_0(E, b, \delta, \varepsilon)$.

We can also consider the same problem for elliptic curves with CM. In this case, we easily obtain an unconditional result by using the bound (1.6) of Pomerance for pseudoprimes and a result of Kowalski [12] about the second moment of $M_E(n)$ for elliptic curves with CM.

**Theorem 1.5** Let $E$ be an elliptic curve over $\mathbb{Q}$ with CM and $b \geq 2$ be an integer. Then we have

$$\pi_{E,b}^\text{pseudo}(x) \leq \frac{x}{L(x)^{1/4}}$$

for all $x \geq x_0(E, b)$.

It seems be interesting to prove that $\pi_{E,b}^\text{pseudo}(x) \to \infty$, as $x \to \infty$. We hope to come back to this question in the future.
2 Chebotarev Density Theorem

In order to prove Theorems 1.1 and 1.3 we need to know some information about the distribution of the sequence \( \{ n_E(p) \} \) of primes in arithmetic progressions. The aim of this section is to give such results with the help of the Chebotarev density theorem. Our main result of this section is Theorem 2.4.

We conserve all the notation of [5 Sections 2 and 3]. In particular, for an elliptic curve \( E \) without complex multiplication defined over the rationals, let \( E[n] \) be the group of \( n \)-torsion points of \( E \), and let \( L_n \) be the field extension obtained from \( \mathbb{Q} \) by adding the coordinates of the \( n \)-torsion of \( E \). This is a Galois extension of \( \mathbb{Q} \), and we let \( G(n) := \text{Gal}(L_n/\mathbb{Q}) \). Since \( E[n](\overline{\mathbb{Q}}) \simeq \mathbb{Z}/n\mathbb{Z} \times \mathbb{Z}/n\mathbb{Z} \), choosing a basis for the \( n \)-torsion and looking at the action of the Galois automorphisms on the \( n \)-torsion, we get an injective homomorphism

\[
\rho_n : G(n) \rightarrow \text{GL}_2(\mathbb{Z}/n\mathbb{Z}).
\]

If \( p \nmid nN_E \), then \( p \) is unramified in \( L_n/\mathbb{Q} \). Let \( p \) be an unramified prime, and let \( \sigma_p \) be the Artin symbol of \( L_n/\mathbb{Q} \) at the prime \( p \). For such a prime \( p \), \( \rho_n(\sigma_p) \) is a conjugacy class of matrices of \( \text{GL}_2(\mathbb{Z}/n\mathbb{Z}) \). Since the Frobenius endomorphism \((x, y) \mapsto (x^p, y^p)\) of \( E \) over \( \mathbb{F}_p \) satisfies the polynomial \( x^2 - a_E(p)x + p \), it is not difficult to see that

\[
\text{tr}(\rho_n(\sigma_p)) \equiv a_E(p) \pmod{n} \quad \text{and} \quad \det(\rho_n(\sigma_p)) \equiv p \pmod{n}.
\]

To study the sequence \( \{ n_E(p) \} \) of primes, we will use the Chebotarev Density Theorem to count the number of primes \( p \) such that

\[
n_E(p) = p + 1 - a_E(p) \equiv \det(\rho_n(\sigma_p)) + 1 - \text{tr}(\rho_n(\sigma_p)) \equiv r \pmod{n}
\]

for integers \( r, n \) with \( n \geq 2 \). We then define

\[
C_r(n) = \{ g \in G(n) : \det(g) + 1 - \text{tr}(g) \equiv r \pmod{n} \}.
\]

Then the \( C_r(n) \) are unions of conjugacy classes in \( G(n) \). We also denote \( C(n) := C_0(n) \). For any prime \( \ell \) such that \((\ell, M_E) = 1, G(\ell) = \text{GL}_2(\mathbb{Z}/\ell\mathbb{Z}) \), and it is easy to compute that

\[
|C_r(\ell)| = \begin{cases} 
\ell(\ell^2 - 2) & \text{for } r \equiv 0 \pmod{\ell}, \\
\ell(\ell^2 - \ell - 1) & \text{for } r \equiv 1 \pmod{\ell}, \\
\ell(\ell^2 - \ell - 2) & \text{for } r \equiv 0, 1 \pmod{\ell},
\end{cases}
\]

and then

\[
\frac{|C_r(\ell)|}{|G(\ell)|} = \begin{cases} 
\frac{\ell^2 - 2}{(\ell - 1)^2(\ell + 1)} & \text{for } r \equiv 0 \pmod{\ell}, \\
\frac{\ell^2 - \ell - 1}{(\ell - 1)^2(\ell + 1)} & \text{for } r \equiv 1 \pmod{\ell}, \\
\frac{\ell^2 - \ell - 2}{(\ell - 1)^2(\ell + 1)} & \text{for } r \equiv 0, 1 \pmod{\ell}.
\end{cases}
\]
It was shown by Serre [19] that the Galois groups $G(n) \subseteq \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$ are large, and that there exists a positive integer $M_E$ depending only on the elliptic curve $E$ such that

If $(n, M_E) = 1$, then $G(n) = \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$;
If $(n, M_E) = (n, m) = 1$, then $G(mn) \simeq G(m) \times G(n)$;

(2.3) If $M_E \mid m$, then $G(m) \subseteq \text{GL}_2(\mathbb{Z}/m\mathbb{Z})$ is the full inverse image of $G(M_E) \subseteq \text{GL}_2(\mathbb{Z}/M_EM_Z)$ under the projection map.

Let

$$
\pi_{C_r}(n, L_n/\mathbb{Q}) := \left\{ p \leq x : p \nmid nN_E \quad \text{and} \quad \rho_p(\sigma_p) \in C_r(n) \right\}.
$$

The following proposition (with a better error term) was proved in [5] Theorem 3.9 for the conjugacy class $C(n) = C_0(n) \subseteq G(n)$ when $n$ is squarefree, and can be easily generalised to general $n$ and $r$.

**Proposition 2.1** Let $E$ be an elliptic curve over $\mathbb{Q}$ without CM. Let $r \geq 0$ be an integer, and let $n = dm$ be any positive integer with $(d, M_E) = 1$ and $m \mid M_E^\infty$.

(i) Then

$$
\pi_{C_r}(n, L_n/\mathbb{Q}) = \frac{|C_r(m)|}{|G(m)|} \left( \prod_{\ell \mid d} \frac{|C_r(\ell^k)|}{|\text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \right) \text{Li}(x) + O_E\left( x \exp\left\{ -A n^{-2} \sqrt{\log x} \right\} \right)
$$

uniformly for $\log x \gg n^{12} \log n$, where the implied constants depend only on the elliptic curve $E$ and $A$ is a positive absolute constant.

(ii) Assuming the GRH for the Dedekind zeta functions of the number fields $L_n/\mathbb{Q}$, we have

$$
\pi_{C_r}(n, L_n/\mathbb{Q}) = \frac{|C_r(m)|}{|G(m)|} \left( \prod_{\ell \mid d} \frac{|C_r(\ell^k)|}{|\text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \right) \text{Li}(x) + O_E\left( n^{1/3} x^{1/2} \log (nx) \right)
$$

**Proof** To prove (i) and (ii), one applies the effective Cheboratev Densituy Theorem due to Lagarias and Odlyzko [13] and slightly improved by Serre in [20], as stated in [5] Theorem 3.1 with the appropriate bounds for the discriminants of number fields [20] Proposition 6], and the bound of Stark [21] for the exceptional zero of Dedekind $L$-functions for (i). We refer the reader to [5] for more details.

**Remark 2.2** There are many cases where we can improve the error term in Proposition 2.1(ii) by applying a strategy first used in [20] and [16] to reduce to the case of an extension where Artin’s conjecture holds. The error term then becomes

$$
O_E\left( n^{1/3} x^{1/2} \log (nx) \right).
$$

The notation $d \mid n^\infty$ means that $p \mid d \Rightarrow p \mid n$ and the notation $p^k \mid n$ means that $p^k \mid n$ and $p^{k+1} \nmid n$. 

---

https://doi.org/10.4153/CJM-2011-044-x Published online by Cambridge University Press
This can be done if \( r = 0 \) (as in [5] Theorem 3.9]), or if \( (n, M_E) = 1 \) for any \( r \). To apply the strategy of [20] and [16] and obtain this improved error term, one needs to ensure that \( C_r(n) \cap B(n) \neq \emptyset \), where \( B(n) \) is the Borel subgroup of \( \text{GL}_2(\mathbb{Z}/n\mathbb{Z}) \). For example, this is the case if \( E \) is a Serre curve, and most elliptic curves are Serre curves as was shown by Jones [10].

We now need upper and lower bounds on the size of the main term of Proposition 2.1, which are computed in the next lemma.

**Lemma 2.3** Let \( E \) be an elliptic curve over \( \mathbb{Q} \) without CM. For all primes \( \ell \nmid M_E \) and integers \( k \geq 1 \), we have the bounds

\[
\frac{1}{\varphi(\ell^k)} \cdot \frac{\ell - 2}{\ell - 1} \leq \frac{|C_r(\ell^k)|}{|\text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \leq \frac{1}{\varphi(\ell^k)} \cdot \frac{\ell - 2}{\ell - 1} \leq \frac{1}{\varphi(\ell^k)} \cdot \frac{1}{(\ell^3 - 1)(\ell^2 - 1)},
\]

when \( r \neq 0 \) (mod \( \ell \)), and the bounds

\[
\frac{1}{\varphi(m)} \cdot \frac{\ell - 2}{\ell - 1} \leq \frac{|C_r(\ell^k)|}{|\text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \leq \frac{1}{\varphi(m)} \cdot \frac{1}{(\ell^3 - 1)(\ell^2 - 1)},
\]

when \( r \equiv 0 \) (mod \( \ell \)).

Furthermore, for \( m \mid M_E \) such that \( |C_r(m)| \neq 0 \), we have that

\[
\frac{1}{\varphi(m)} \ll_E \frac{|C_r(m)|}{|G(m)|} \ll_E \frac{1}{\varphi(m)}
\]

with constants depending only on the elliptic curve \( E \). In particular, the upper bound in (2.6) holds without the hypothesis \( |C_r(m)| \neq 0 \).

**Proof** Fix \( \ell \nmid M_E \) and \( k \geq 1 \). To count the number of elements in \( C_r(\ell^k) \), we count the matrices \( g \in \text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z}) \) which are the inverse images of a matrix \( g \in C_r(\ell) \) under the projection map from \( \text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z}) \) to \( \text{GL}_2(\mathbb{Z}/\ell\mathbb{Z}) \), and which satisfy

\[
\det(g) + 1 = \text{tr}(g) \equiv r \pmod{\ell^k}.
\]

Let

\[
g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad \tilde{g} = \begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix}.
\]

If \( b \neq 0 \pmod{\ell} \), then \( \tilde{b} \) is invertible, and we have to count the number of \( \tilde{a}, \tilde{b}, \tilde{c}, \tilde{d} \) lifting \( a, b, c, d \) such that \( \tilde{c} \equiv \tilde{b}^{-1}(\tilde{a}\tilde{d} - (\tilde{a} + \tilde{d}) - r + 1) \pmod{\ell^k} \), and there are \( \ell^{3(k-1)} \) such lifts. A similar argument shows that there are also \( \ell^{3(k-1)} \) lifts if \( c \neq 0 \pmod{\ell} \), or \( a \neq 1 \pmod{\ell} \) or \( d \neq 1 \pmod{\ell} \). This proves (2.4) as the identity matrix does not belong to \( C_r(\ell) \) when \( r \neq 0 \pmod{\ell} \). Then the number of lifts of any matrix from \( C_r(\ell) \) to \( C_r(\ell^k) \) is \( \ell^{3(k-1)} \) and the number of lifts from \( \text{GL}_2(\mathbb{Z}/\ell\mathbb{Z}) \) to \( \text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z}) \) is \( \ell^{3(k-1)} \), which gives

\[
\frac{|C_r(\ell^k)|}{|\text{GL}_2(\mathbb{Z}/\ell^k\mathbb{Z})|} = \frac{\ell^{3(k-1)}|C_r(\ell)|}{|\text{GL}_2(\mathbb{Z}/\ell\mathbb{Z})|}.
\]
and the result follows by using (2.2).

Finally, we have to count the number of lifts

\[
\begin{pmatrix}
1 + k_1 \ell & k_2 \ell \\
 k_3 \ell & 1 + k_4 \ell
\end{pmatrix}
\]

of the identity matrix such that \(\ell^2(k_1k_4 - k_2k_3) \equiv r \pmod{\ell^3}\), where \(0 \leq k_i < \ell^{k-1}\). We assume that \(k \geq 2\). If \(r \not\equiv 0 \pmod{\ell^2}\), there are no lifts, and we assume that \(r \equiv 0 \pmod{\ell^2}\). Let \(v = \min_v(v_i)\), where \(v_i(n)\) is the \(\ell\)-adic valuation of \(n\), and write \(k_i = \ell k'_i\) with \(0 \leq k'_i < \ell^{k-1-i}\). If \(r \not\equiv 0 \pmod{\ell^{k+r}}\), there is no solution with \(k_1, k_2, k_3, k_4\) such that \(v = \min_v(v_i(k_i))\). Suppose that \(r \equiv 0 \pmod{\ell^{k+r}}\). Then we need to solve

\[\ell^{k+r}(k'_1k'_4 - k'_2k'_3) \equiv \ell^{k+r}r' \pmod{\ell^3} \iff (k'_1k'_4 - k'_2k'_3) \equiv r' \pmod{\ell^{k-2-r}},\]

and there are \(\ell^{\ell-1-v}\) solutions \(k'_1, k'_2, k'_3, k'_4\). The number of lifts of the identity matrix is then bounded by

\[
\sum_{r=0}^{k-2} \ell^{3(k-1-v)} = \ell^{\ell-1} \sum_{r=0}^{k-2} \ell^{-3v} \leq \ell^{\ell-1} \frac{\ell^3}{\ell^3 - 1}.
\]

We now prove (2.5). Using (2.7) and the first formula of (2.1), it follows that

\[
\frac{\ell^{k-1}|C_{\ell}(\ell^k)|}{|GL_2(\mathbb{Z}/\ell^3\mathbb{Z})|} \leq \frac{|C_{\ell}(\ell)|}{|GL_2(\mathbb{Z}/\ell\mathbb{Z})|} + \frac{\ell^4/(\ell^3 - 1)}{|GL_2(\mathbb{Z}/\ell\mathbb{Z})|} = \frac{(\ell^3 - 1)(\ell^2 - 1) + 1}{(\ell - 1)(\ell^2 - 1)(\ell^3 - 1)}.
\]

For the lower bound, we have

\[
|C_{\ell}(\ell^k)| \geq \frac{|C_{\ell}(\ell)| - 1}{|GL_2(\mathbb{Z}/\ell\mathbb{Z})|} \geq \frac{\ell(\ell^2 - 1) - 1}{\ell(\ell - 1)(\ell^2 - 1)} \geq \frac{\ell - 2}{\ell - 1}^2,
\]

We now prove (2.6). Let \(m' = \prod_{p \mid m} p^{\min\{r_p(m), r_p(M_c)\}}\). By (2.3), \(G(m)\) is the full inverse image of \(G(m')\) under the projection map from \(GL_2(\mathbb{Z}/m\mathbb{Z})\) to \(GL_2(\mathbb{Z}/m'\mathbb{Z})\). Fix \(g \in C_{\ell}(m')\), and we now count the number of lifts \(\bar{g}\) in \(C_{\ell}(m)\). By the Chinese Remainder Theorem, it suffices to count the number of lifts from \(C_{\ell}(p^{r_p(m')})\) to \(C_{\ell}(p^{r_p(m)})\) for each \(p \mid m\). In general, fix \(1 \leq e \leq k\), fix \(g \in GL_2(\mathbb{Z}/p^e\mathbb{Z})\) such that \(\det(g) + 1 - \text{tr}(g) \equiv r \pmod{p^e}\), and we count the number of lifts \(\bar{g} \in GL_2(\mathbb{Z}/p^{e}\mathbb{Z})\) such that \(\det(\bar{g}) + 1 - \text{tr}(\bar{g}) \equiv r \pmod{p^k}\). If \(g\) is not congruent to the identity matrix modulo \(p\), then the same argument as above shows that there are \(p^{3(k-e)}\) lifts of \(g\). If \(g\) is congruent to the identity matrix modulo \(p\), we have to count the number of matrices

\[
\bar{g} = \begin{pmatrix} 1 + k_1 p^e & k_2 p^e \\ k_3 p^e & 1 + k_4 p^e \end{pmatrix}
\]

such that

\[p^{2e}(k_1k_4 - k_2k_3) \equiv r \pmod{p^k},\]
where \( 0 \leq k_i < p^{k-e} \). If \( r \not\equiv 0 \pmod{p^k} \), there are no lifts, and we suppose that \( r \equiv 0 \pmod{p^k} \). Let \( \nu = \min \nu_p(k_i) \), and write \( k_i = \nu_p k_i' \) where \( 0 \leq \nu < k - e \) and \( 0 \leq k_i' < p^{k-e} \). The congruence above can be rewritten as

\[
(2.8) \quad p^{2\nu r}(k_i'k_i' - k_i'k_i'') \equiv r \pmod{p^k}.
\]

If \( 2\nu + \nu \geq k \), (2.8) has \( p^{4(k-e-v)} \) solutions when \( r \equiv 0 \pmod{p^k} \) and no solutions otherwise. If \( 2\nu + \nu < k \), assume that \( r \equiv 0 \pmod{p^{2\nu + \nu}} \) (otherwise (2.8) has no solutions). Writing \( r = r'p^{2\nu + \nu} \), (2.8) rewrites as \( k_i'k_i' - k_i'k_i' \equiv r' \pmod{p^{k-2\nu -\nu}} \) and this leads to \( p^{4(k-e-v)} \) solutions \( k_i', k_i', k_i', k_i' \). Then the number of lifts of the identity matrix from \( \mathbb{C} \) to \( \mathbb{G} \) is bounded by

\[
(2.9) \quad \sum_{v=0}^{k-e-1} p^v p^{4(k-e-v)} + \sum_{v=0}^{k-e-1} p^{4(k-e-v)} \leq p^{3(k-e)}p^{4e+1}.
\]

Then, applying (2.9), we have that

\[
\frac{|C_r(m)|}{|G(m)|} \leq \frac{|C_r(m')|}{|G(m')|} \prod_{p|m} \frac{p^{3\nu_p(m') - \nu_p(m')}}{p^{4\nu_p(m') + 1}} \frac{1}{\phi(m)} \frac{1}{\phi(m')},
\]

Finally we suppose that \( |C_r(m)| \neq 0 \) and prove the lower bound in (2.6). Denoting by \( C_r(m') \neq \) the subset of \( C_r(m') \) consisting of matrices not equivalent to the identity matrix modulo \( p \) (notice that \( C_r(m') \neq \) is not empty, since \( |C_r(m)| \neq 0 \)), we have that

\[
\frac{|C_r(m)|}{|G(m)|} \geq \frac{|C_r(m')|}{|G(m')|} \prod_{p|m} \frac{p^{3\nu_p(m') - \nu_p(m')}}{p^{4\nu_p(m') + 1}} \frac{1}{\phi(m)} \frac{1}{\phi(m')},
\]

and the lower bound in (2.6) follows from the last two inequalities.

**Theorem 2.4** Let \( E \) be an elliptic curve over \( \mathbb{Q} \) without CM. Let \( r \geq 0 \) be an integer, and let \( n = dm \) be any positive integer with \( (d, M_E) = 1 \) and \( m \mid M_E^n \).

(i) We have that

\[
\left| \left\{ p \leq x : n_E(p) \equiv r \pmod{m} \right\} \right| \ll_E \frac{\log x}{\phi(n)} + x \exp \left\{ -An^{-2}\sqrt{\log x} \right\}
\]

uniformly for \( \log x \gg n^{12}\log n \), where the implied constants depend only on the elliptic curve \( E \) and \( A \) is a positive absolute constant.
(ii) Assuming the GRH for the Dedekind zeta functions of the number fields $L_n/Q$, we have that

$$
\left| \left\{ p \leq x : n_E(p) \equiv r \pmod{n} \right\} \right| \ll_E \frac{\operatorname{Li}(x)}{\varphi(n)} + n^{3/2} x^{1/2} \log(nx).
$$

(iii) Assuming the GRH for the Dedekind zeta functions of the number fields $L_n/Q$, we have that

$$
\left| \left\{ p \leq x : n_E(p) \equiv r \pmod{n} \right\} \right| \ll_E \frac{\operatorname{Li}(x)}{\varphi(n)}
$$

holds uniformly for $n \leq x^{1/8}/\log x$, where the implied constant depends only on the elliptic curve $E$.

Further, if $r = 0$ or $(n,M_E) = 1$, then the condition $n \leq x^{1/8}/\log x$ in the third assertion can be relaxed to $n \leq x^{1/5}/\log x$ and the term $n^{3/2} x^{1/2} \log(nx)$ in the second can be replaced by $n^{3/2} x^{1/2} \log(nx)$.

**Proof** It follows from the estimates of Lemma 2.3 that

$$
\frac{|C_r(m)|}{|G(m)|} \left( \prod_{\ell \parallel d} \frac{|C_r(\ell^k)|}{|GL_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \right) \ll_E \frac{1}{\varphi(d)} \frac{1}{\varphi(m)} = \frac{1}{\varphi(n)},
$$

and first two statements are obtained by using this upper bound in the estimates of Proposition 2.1 for

$$
\pi_{C_r(n)}(x, L_n/Q) = \left| \left\{ p \leq x : n_E(p) = p + 1 - a_E(p) \equiv r \pmod{n} \right\} \right|.
$$

We now prove (iii). If $|C_r(m)| = 0$, Proposition 2.1 implies trivially the required inequality, and we suppose that $|C_r(m)| \neq 0$. Clearly, it is sufficient to show that

$$
\frac{1}{\varphi(n) \log_2 n} \ll_E \frac{|C_r(m)|}{|G(m)|} \left( \prod_{\ell \parallel d} \frac{|C_r(\ell^k)|}{|GL_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \right) \ll_E \frac{1}{\varphi(n)}.
$$

It follows from Lemma 2.3 that

$$
\frac{1}{\varphi(d)} \prod_{\ell \parallel d} \frac{\ell - 2}{\ell - 1} \ll \prod_{\ell \parallel d} \frac{|C_r(\ell^k)|}{|GL_2(\mathbb{Z}/\ell^k\mathbb{Z})|} \ll \frac{1}{\varphi(d)},
$$

and the lower bound of (2.10) follows from (2.11), (2.6), and the estimate

$$
\prod_{\ell \parallel d} \frac{\ell - 2}{\ell - 1} \gg \prod_{\ell \parallel d} \frac{\ell - 2}{\ell - 1} \gg \frac{1}{\log_2 n}.
$$

This completes the proof of the theorem.
3 Rosser–Iwaniec Linear Sieve Formulas

In this section we state the Rosser–Iwaniec linear sieve \([9, \text{Theorem 1}]\), which will be used in the proof of Theorem 1. It is worth noting that the Selberg linear sieve \([8, \text{Theorem 8.4}]\) cannot be applied for our purpose, since the condition \((\Omega_2(1, L))\) of Selberg's linear sieve (see \([8, \text{p. 228}]\)) is not satisfied by the function \(w_y(\ell)\). But the corresponding condition \((\Omega_1)\) of the Rosser–Iwaniec sieve is satisfied by the \(w_y(\ell)\) (see (4.2)).

Let \(A\) be a finite sequence of integers and \(\mathcal{P}\) a set of prime numbers. As usual, we write the sieve function

\[
S(A, \mathcal{P}, z) := |\{a \in A : (a, P(z)) = 1\}|
\]

where \(P(z) := \prod_{p \leq z, p \in \mathcal{P}} p\). Let \(\mathcal{B} = \mathcal{B}(\mathcal{P})\) denote the set of all positive squarefree integers supported on the primes of \(\mathcal{P}\). For each \(d \in \mathcal{B}\), define

\[
A_d := \{a \in A : a \equiv 0 \mod{d}\}.
\]

We assume that \(A\) is well distributed over arithmetic progressions \(0 \mod{d}\) in the following sense: There is a convenient approximation \(X\) to \(|A|\) as well as a multiplicative function \(w(d)\) on \(\mathcal{B}\) verifying\(^4\)

\[
(A_0) \quad 0 < w(p) < p \quad (p \in \mathcal{P})
\]

such that

(i) the “remainders”

\[
(3.1) \quad r(A, d) := |A_d| - \frac{w(d)}{d} X \quad (d \in \mathcal{B})
\]

are small on average over the divisors \(d\) of \(P(z)\);

(ii) there exists a constant \(K \geq 1\) such that

\[
(\Omega_1) \quad \frac{V(z_1)}{V(z_2)} \leq \frac{\log z_2}{\log z_1} \left(1 + \frac{K}{\log z_1}\right) \quad (2 \leq z_1 < z_2),
\]

where

\[
V(z) := \prod_{p < z} \left(1 - \frac{w(p)}{d}\right).
\]

The next result is the well-known theorem of Iwaniec \([9, \text{Theorem 1}]\).

**Lemma 3.1** Under the hypotheses \((A_0)\), \((3.1)\), and \((\Omega_1)\), we have

\[
S(A, \mathcal{P}, z) \leq XV(z) \{F(s) + E\} + 2^{-s} R(A, M, N),
\]

\(^4\)Since we need \((3.1)\) below only for \(d \mid P(z)\), we are free to define \(w(p) = 0\) for \(p \notin \mathcal{P}\).
where $0 < \varepsilon < \frac{1}{8}$, $s := (\log MN)/\log z$, $E \ll \varepsilon s^2 e^K + \varepsilon^{-8} e^{K-1} (\log MN)^{-1/3}$, and

$$F(s) = \frac{2e^\gamma}{s} \quad (0 < s \leq 3), \quad V(z) := \prod_{p < z} \left( 1 - \frac{w(p)}{d} \right).$$

The second error term $R(A, M, N)$ has the form

$$R(A, M, N) := \sum_{m<n<z} a_m b_n r(A, mn),$$

where the coefficients $a_m, b_n$ are bounded by 1 in absolute value and depend at most on $M, N, z, \text{and} \ \varepsilon$.

### 4 Proof of Theorem 1.1

As in [3], introduce $L := \prod_{y \leq \ell < z} \ell$ and

$$S(x, y, z) := \{ p \leq x : (n_E(p), L) = 1 \},$$

$$T(x, y, z) := \{ p \leq x : (n_E(p), L) > 1, b_{n_E(p)} \equiv b \mod{n_E(p)} \}. $$

Clearly,

$$(4.1) \quad Q_{E,b}(x) \leq |S(x, y, z)| + |T(x, y, z)|.$$ 

First we estimate $|S(x, y, z)|$.

**Lemma 4.1** Let $E$ be an elliptic curve over $\mathbb{Q}$ without CM and $b \geq 2$ be an integer. For any $\varepsilon$, there is a constant $y_0 = y_0(E, b, \varepsilon)$ such that the following hold:

(i) We have

$$|S(x, y, z)| \leq (e^\gamma + \varepsilon) \frac{x \log y}{(\log x) \log z}$$

uniformly for $y_0 \leq y \leq z \leq (\log x)^{1/24}/\log_2 x$.

(ii) If we assume the GRH, we have

$$|S(x, y, z)| \leq (e^\gamma + \varepsilon) \frac{x \log y}{(\log x) \log z}$$

uniformly for $y_0 \leq y \leq z \leq x^{1/10}/(\log x)^4$.

**Proof** We shall sieve

$$\mathcal{A} := \{ n_E(p) : p \leq x \} \quad \text{by} \quad \mathcal{P}_y := \{ p : p \geq y \}.$$ 

By definition, $|S(x, y, z)| = S(\mathcal{A}, \mathcal{P}_y, z)$ for all $1 \leq y \leq z \leq x$. 

https://doi.org/10.4153/CJM-2011-044-x Published online by Cambridge University Press
Without loss of generality, we can suppose that $y_0 \geq M_E + b$. Thus we have $(d, M_E) = 1$ for all $d \in \mathcal{B}(y)$. Using Proposition 2.1 (with the improved error term discussed in the remark following the proposition under the GRH) and (2.2), we get that

$$|\mathcal{A}_d| = \frac{w_y(d)}{d} X + r(\mathcal{A}, d)$$

for all $d \in \mathcal{B}(y)$, with

$$X = \text{Li}(x),$$

$$w_y(\ell) = \frac{\ell(\ell^2 - 2)}{(\ell - 1)(\ell^2 - 1)} \quad (\ell \in \mathcal{P}_y),$$

(4.2)

$$|r(\mathcal{A}, d)| \ll_E \begin{cases} x e^{-A\sqrt{\log x}} & (d \leq (\log x)^{1/12}/\log x), \\ d^{3/2} x^{1/2} \log(dx) & (\text{under the GRH}) \end{cases}$$

where $A > 0$ is a positive absolute constant.

In order to apply Lemma 3.1, we must show that $w_y(\ell)$ satisfies conditions $(A_0)$ and $(\Omega_1)$. The former is obvious, and we now check the latter. Writing

(4.3)

$$V_y(z) := \prod_{p < z} \left(1 - \frac{w_y(p)}{p}\right)^{-1},$$

then

$$\frac{V_y(z_1)}{V_y(z_2)} \leq \frac{V_1(z_1)}{V_1(z_2)}$$

for all $z_2 > z_1 \geq 2$. On the other hand, by using the prime number theorem, it follows that

(4.4)

$$V_1(z) = \prod_{p < z} \left(1 - \frac{w_1(p)}{p}\right) = \prod_{p < z} \left(1 - \frac{1}{p}\right) \prod_{p < z} \left(1 - \frac{p^2 - p - 1}{(p - 1)^3(p + 1)}\right)$$

$$= \left\{1 + O\left(\frac{1}{\log z}\right)\right\} C e^{-\gamma} \log z,$$

where $\gamma$ is the Euler constant and

$$C := \prod_p \left(1 - \frac{p^2 - p - 1}{(p - 1)^3(p + 1)}\right).$$

Clearly this implies that for any $2 \leq z_1 < z_2$

(4.5)

$$\frac{V_1(z_1)}{V_1(z_2)} = \log z_2 \log z_1 \left\{1 + O\left(\frac{1}{\log z_1}\right)\right\},$$
and (4.3) and (4.5) show that condition \((\Omega_1)\) is satisfied. Therefore we can apply Lemma 3.1 to write

\[
S(\mathscr{A}, \mathcal{P}_y, z) \leq (e^\gamma + \varepsilon) XV_y(z) + R_S,
\]

where

\[
R_S := \sum_{\delta < z, \delta \mid P(z)} 2^\omega(d)|r(\mathscr{A}, d)|.
\]

In view of the bounds for \(|r(\mathscr{A}, d)|\) of (4.2), we can deduce that

\[
R_S \ll x / (\log x)^3
\]

for all

\[
z \leq \begin{cases} (\log x)^{1/24} / \log x & \text{(unconditionally),} \\ x^{1/10} / (\log x)^4 & \text{(under GRH).} \end{cases}
\]

On the other hand, in view of (4.4), we have for any \(z > y\),

\[
V_y(z) = \frac{V_1(z)}{V_1(y)} = \left\{1 + O\left(\frac{1}{\log y}\right)\right\} \frac{\log y}{\log z}
\]

Inserting (4.7) and (4.9) into (4.6), we obtain the required results. \(\blacksquare\)

In order to estimate \(|T(x, y, z)|\), we need to prove a preliminary result. For integers \(b \geq 2 \) and \(d \geq 1\), denote by \(\text{ord}_d(b)\) the multiplicative order of \(b\) modulo \(d\) (i.e., the smallest positive integer \(k\) with \(b^k \equiv 1 \pmod{d}\)).

**Lemma 4.2** For all \(t \geq 1\), we have

\[
\sum_{\ell \leq t} \frac{1}{\ell \text{ord}_\ell (b)} \ll b \frac{1}{t^{1/2}},
\]

\[
\sum_{\ell \geq t} \frac{1}{\ell \text{ord}_\ell (b)} \ll b \frac{1}{t^{1/3}}.
\]

**Proof** Let \(0 < \eta < 1\) be a parameter to be chosen later. We have

\[
\sum_{\text{ord}_d(b) = m} 1 \leq \sum_{\ell \mid (b^m - 1)} 1 \leq \frac{\log(b^m - 1)}{\log 2} \leq \frac{\log b}{\log 2} m.
\]

Thus

\[
\sum_{\ell \leq u, \ell \leq \text{ord}_\ell (b) < \ell^\eta} \frac{1}{\text{ord}_\ell (b)} = \sum_{m \leq u^\eta} \frac{1}{m} \sum_{\ell \leq u, \ell \leq \text{ord}_\ell (b) = m} 1 \leq \sum_{m \leq u^\eta} \frac{\log b}{\log 2} \ll b \eta u^\eta.
\]
A simple partial summation leads to

\[ \sum_{\ell \geq t \atop \text{ord}_\ell(b) < t^\eta} \frac{1}{\ell \text{ord}_\ell(b)} = \int_t^\infty \frac{1}{u} \left( \sum_{\ell \leq u \atop \text{ord}_\ell(b) < t^\eta} \frac{1}{\ell \text{ord}_\ell(b)} \right) \ll b, t^{1-\eta}. \]

On the other hand, we have trivially

\[ \sum_{\ell \geq t \atop \text{ord}_\ell(b) < t^\eta} \frac{1}{\ell \text{ord}_\ell(b)} \ll \sum_{\ell \geq t} \frac{1}{\ell^1/\eta} \ll \eta^{-1}. \]

Combining these estimates and taking \( \eta = \frac{1}{2} \), we obtain \((4.10)\).

Similarly we have

\[ \sum_{\ell \geq t \atop \text{ord}_\ell(b) < t^\eta} \frac{1}{\ell \text{ord}_\ell(b)} \ll \sum_{\ell \geq t^{1/(1+\eta)}} \frac{1}{\ell \text{ord}_\ell(b)} \ll b, t^{(1-\eta)/(1+\eta)}. \]

The inequality \((4.11)\) follows from these estimates with the choice of \( \eta = \frac{1}{2} \).

We now estimate \(|T(x, y, z)|\).

\textbf{Lemma 4.3} Let \( E \) be an elliptic curve over \( \mathbb{Q} \) without CM and \( b \geq 2 \) be an integer. Then there is a constant \( y_0 = y_0(E, b) \) and a positive absolute constant \( A \) such that the following hold:

(i) We have

\[ |T(x, y, z)| \ll_{E, b} \text{Li}(x) \frac{\log z}{y^{1/2}} + x \exp \left\{ -A z^{-4} \sqrt{\log x} \right\} \]

uniformly for

\[ y_0 \leq y < z \leq (\log x)^{1/4}/\log_2 x. \]

(ii) If we assume the GRH, we have

\[ |T(x, y, z)| \ll_{E, b} \text{Li}(x) \frac{\log z}{y^{1/2}} + z^2 x^{1/2} \]

uniformly for \( y_0 \leq y < z \).

\[ \frac{1}{\ell \text{ord}_\ell(b)} \ll \frac{1}{\ell^{1+\eta}} \ll \eta^{-1/\eta}. \]

\[ \ll \frac{1}{\ell^{1/(1+\eta)}} \ll \eta^{1/(1+\eta)}. \]
The implied constants depend on $E$ and $b$ only.

**Proof**  If $n_E(p)$ is a pseudoprime to base $b$ and $d \mid n_E(p)$ with $(d, b) = 1$, then

$$d \mid n_E(p) \mid b^{n_E(p) - 1} - 1 \Rightarrow d \mid (b^{n_E(p)} - 1) \Rightarrow b^{n_E(p) - 1} \equiv 1 \pmod{d}.$$  

Using Fermat’s little theorem, it follows that

$$n_E(p) \equiv 0 \pmod{d}, \quad n_E(p) \equiv 1 \pmod{\text{ord}_d(b)}, \quad (d, \text{ord}_d(b)) = 1.$$

By the Chinese remainder theorem, there is an integer $r_{b,d} \in \{1, \ldots, d \text{ord}_d(b)\}$ such that

$$n_E(p) \equiv r_{b,d} \pmod{d \text{ord}_d(b)}.$$

Clearly for each $p \in \mathcal{T}(x, y, z)$, there is a prime $\ell$ such that

$$y \leq \ell < z, \quad \ell \mid (L, n_E(p)), \quad \text{and} \quad n_E(p) \mid b^{n_E(p) - 1} - 1.$$

Applying (4.14) with $d = \ell$, we have

$$|\mathcal{T}(x, y, z)| \leq \sum_{y < \ell \leq z} \sum_{n_E(p) \equiv r_{b,d} \pmod{d \text{ord}_d(b)}} 1 = \sum_{y < \ell \leq z} \pi_{C_{b,y}}(x, L_{\ell \text{ord}_d(b)}/Q).$$

Then, using Theorem 2.4(i) and (ii) with the bound $\varphi(n) \gg n/\log_2 n$, we have that

$$|\mathcal{T}(x, y, z)| \ll E \text{Li}(x)(\log_2 z) \sum_{y < \ell \leq z} \frac{1}{\ell \text{ord}_d(b)} + R_T,$$

where

$$R_T := \begin{cases} \sum_{y < \ell \leq z} x \exp \left\{ -A\ell^{-4} \sqrt{\log x} \right\} \quad (z \leq (\log x)^{1/24}/\log_2 x), \\ \sum_{y < \ell \leq z} \ell^6(x^{1/2} \log(\ell^2 x)) \quad \text{(under the GRH)}, \end{cases}$$

$$\ll \begin{cases} x \exp \left\{ -Az^{-4} \sqrt{\log x} \right\} \quad (z \leq (\log x)^{1/24}/\log_2 x), \\ z^2 x^{1/2} \quad \text{(under the GRH)}. \end{cases}$$

The required results follow from (4.15), (4.16), and (4.10) of Lemma 4.2.\[\square\]

Taking, in Lemmas 4.1 and 4.3

$$y = \begin{cases} (\log_2 x)^2 \log_3 x \quad \text{(unconditionally),} \\ (\log x)^2 \log_2 x \quad \text{(under the GRH)}, \end{cases}$$

$$z = \begin{cases} (\log x)^{1/24}/\log_2 x \quad \text{(unconditionally),} \\ x^{1/14}/\log x \quad \text{(under the GRH)}, \end{cases}$$

which satisfy (4.11) and (4.13), and using the bounds of those lemmas in (4.1), this proves Theorem 1.1.
5 Proof of Theorem \textbf{1.3}

We shall adapt Pomerance’s method in [17] to prove Theorem \textbf{1.3}.

We split the primes $p \leq x$, such that $n_E(p)$ is pseudoprime to base $b$, into four possibly overlapping classes:

- $n_E(p) \leq x/L(x)$;
- there is $\ell \mid n_E(p)$ with $\text{ord}_\ell(b) \leq L(x)$ and $\ell > L(x)^3$;
- there is $\ell \mid n_E(p)$ with $\text{ord}_\ell(b) > L(x)$;
- $n_E(p) > x/L(x)$, for all $\ell \mid n_E(p)$, we have $\ell \leq L(x)^3$;

and denote by $S_1, \ldots, S_4$ the corresponding contribution to $\pi_{E,b}^{\text{pseu}}(x)$, respectively.

A. Estimate for $S_1$

In view of (1.9), it follows that

\begin{equation}
S_1 \leq \sum_{p \leq 16x/L(x)} 1 \ll \frac{x}{L(x)}.
\end{equation}

B. Estimate for $S_2$

Clearly,

\begin{equation}
S_2 \ll \sum_{\ell > L(x)^3} \sum_{p \leq x \atop \text{ord}_\ell(b) \leq L(x) \atop \ell \mid n_E(p)} 1.
\end{equation}

Using Theorem 2.4(iii) with $r = 0$ and (4.12), we deduce that the contribution of $L(x)^3 < \ell \leq x^{1/5}/\log x$ to $S_2$ is

\begin{equation}
\ll E \sum_{L(x)^3 < \ell \leq x^{1/5}/\log x} \frac{\text{Li}(x)}{\ell} \ll E \frac{x}{L(x)^3} \sum_{p \leq x \atop \text{ord}_p(b) \leq L(x)} 1 \ll E b \frac{x}{L(x)}.
\end{equation}

Furthermore, using Hypothesis 1.2 with $\delta < \frac{1}{5}$, we have

\begin{align*}
\sum_{x^{1/5}/\log x < \ell \leq x} & \sum_{p \leq x \atop \text{ord}_p(b) \leq L(x) \atop \ell \mid n_E(p)} 1 \\
\ll E & \sum_{x^{1/5}/\log x < \ell \leq x} \sum_{m \leq 2x/\ell \atop \text{ord}_\ell(b) \leq L(x)} \sum_{p \leq x \atop n_E(p) = m\ell} 1 \\
& \ll E \sum_{x^{1/5}/\log x < \ell \leq x} \sum_{m \leq 2x/\ell \atop \text{ord}_\ell(b) \leq L(x)} (m\ell)^\delta \\
\ll E & \sum_{x^{1/5}/\log x < \ell \leq x} \sum_{m \leq 2x/\ell \atop \text{ord}_\ell(b) \leq L(x)} \frac{x^{1+\delta}}{\ell} \\
\ll E b & x^{1/5+\delta} L(x)^3
\end{align*}

using (4.12).

Combining these estimates yields

\begin{equation}
S_2 \ll E b \frac{x}{L(x)}.
\end{equation}
C. Estimate for $S_3$

Clearly,

$$S_3 \leq \sum_{n \leq 4x, \exists \left( n \text{ with ord}_d(n) > \log n \right)} \sum_{p \leq x} 1.$$ 

If $n$ is a pseudoprime and $d \mid n$, then

$$n \equiv 0 \pmod{d}, \quad n \equiv 1 \pmod{\text{ord}_d(b)}, \quad (d, \text{ord}_d(b)) = 1.$$

Thus the number of pseudoprimes $n \leq 4x$ with $d \mid n$ at most $1 + 4x/(d \text{ord}_d(b))$. If $d = \ell$, a prime, then we throw out the solution $n = \ell$ to (5.3), so that in this case there are at most $4x/\ell \text{ord}_d(b)$ solutions in pseudoprimes $n$. Then, if $\ell \text{ord}_d(b) > 4x$, there are no solution in pseudoprimes $n$ and no contribution to $S_3$, and we can suppose that $\ell \text{ord}_d(b) \leq 4x$. Thus,

$$S_3 \leq \sum_{\ell \text{ord}_d(b) \leq 4x} \sum_{\ell \mid n} \sum_{p \leq x} 1 \leq \sum_{\ell \text{ord}_d(b) \leq 4x} \sum_{p \leq 4x, \ell \mid n} 1.$$ 

Applying (4.14) with $d = \ell$, there is an integer $r_{b,\ell} \in \{1, \ldots, \ell \text{ord}_d(b)\}$ such that $n \ell \equiv r_{b,\ell} \pmod{\ell \text{ord}_d(b)}$. Thus

$$S_3 \leq \sum_{\ell \text{ord}_d(b) \leq 4x} \sum_{p \leq x} 1.$$ 

If $\ell \text{ord}_d(b) \leq x^{1/8}/\log x$, then by Theorem 2.4 iii)

$$\sum_{p \leq x} 1 \ll \frac{\log x}{\ell \text{ord}_d(b)}.$$ 

and using again the bound $\varphi(n) \gg n/\log_2 n$, the contribution of those $\ell$ to $S_3$ is bounded by

$$\sum_{\ell \text{ord}_d(b) \leq x^{1/8}/\log x} \frac{\log x}{\ell \text{ord}_d(b)} \ll \frac{\log x}{\ell} \sum_{\ell \text{ord}_d(b) \leq x^{1/8}/\log x} 1 \ll \frac{\log x (\log x)^2}{L(x)}.$$
With the help of Hypothesis 1.2 with \( \delta < \frac{1}{2} \) and (4.11) of Lemma 4.2, the contribution of \( x^{1/8} / \log x < \ell \text{ ord}_L(b) \leq 4x \) to \( S_3 \) is bounded by

\[
\sum_{x^{1/8} / \log x < \ell \text{ ord}_L(b) \leq 4x} \sum_{0 \leq m \leq 4x / \ell \text{ ord}_L(b)} \sum_{p \leq x} 1 \ll_E \sum_{x^{1/8} / \log x < \ell \text{ ord}_L(b) \leq 4x} \sum_{0 \leq m \leq 4x / \ell \text{ ord}_L(b)} (r_{b, \ell} + m(\ell \text{ ord}_L(b)))^\delta
\]

\[
\ll_E \frac{x^{1+\delta}}{\ell \text{ ord}_L(b)}
\]

\[
\ll_E x^{1+\delta} - 1/24 \log x.
\]

Inserting these estimates into (5.4), we find that

(5.5)

\[
S_3 \ll_E \frac{x}{L(x)}.
\]

D. Estimate for \( S_4 \)

In order to adapt the proof of [17] to the more general definition (1.3) of pseudoprimes (which includes the case where \( b \) and \( n \) are not coprime), we write \( n_E(p) = n_E^r(p) n_E^m(p) \) with \( n_E^r(p) \mid b^\infty \) and \( (n_E^m(p), b) = 1 \). Denote by \( S_4^r \) and \( S_4^m \) the contribution of \( n_E^r(p) > x^{1/3} \) and \( n_E^m(p) \leq x^{1/3} \) to \( S_4 \), respectively.

By the Hasse bound (formulated as the statement of Hypothesis 1.2 with \( \delta = \frac{1}{2} \)), we have

\[
S_4^r \ll \sum_{x^{1/3} < d \leq 4x} \sum_{d \mid p^\infty} \sum_{m \leq 4x / d} 1 \ll E \sum_{x^{1/3} < d \leq 4x} \sum_{m \leq 4x / d} (dm)^{1/2}
\]

\[
\ll \sum_{x^{1/3} < d \leq 4x} \frac{x^{3/2}}{d} \ll x^{5/6} (\log x)^{h}.
\]

If \( p \) is counted in \( S_4^r \), then \( n_E^r(p) > x^{1/3} / L(x) \) and all prime factors of \( n_E^r(p) \) are \( \leq L(x)^3 \). Thus \( n_E^r(p) \) must have a divisor \( d \) with \( x^{1/18} < d < x^{1/17} \) and \( (d, b) = 1 \). Thus, by the comment following (4.14), \( n_E(p) \equiv r_{b,d} \text{ (mod d ord}_d(b)) \) for some residue \( r_{b,d} \), and by Theorem 2.4 we have

\[
S_4^r \ll \sum_{x^{1/18} < d \leq x^{1/17}} \sum_{(d, b) = 1} \sum_{n_E(p) \equiv r_{b,d} \text{ (mod d ord}_d(b))} 1 \ll_E \sum_{x^{1/18} < d \leq x^{1/17}} \frac{x}{d \text{ ord}_d(b)}
\]

\[
\ll x \sum_{m \leq x^{1/17}} \frac{1}{m} \sum_{x^{1/18} < d \leq x^{1/17}} \frac{1}{d}.
\]
With the help of the following inequality (see [17, Theorem 1])

$$\sum_{d \leq t \atop \text{ord}_d(b) = m} 1 \leq \frac{t}{\sqrt{L(t)}} \quad (t \geq t_0(b), m \geq 1),$$

a simple partial integration allows us to deduce that

$$\sum_{x^{1/18} \leq d \leq x^{1/17} \atop \text{ord}_d(b) = m} \frac{1}{d} = \int_{x^{1/18}}^{x^{1/17}} \frac{1}{t} \left( \sum_{d \leq t \atop \text{ord}_d(b) = m} 1 \right) \ll \frac{1}{L(x)^{1/57}},$$

and $S''_4 \ll_E x (\log x) L(x)^{-1/37}$. Thus

(5.6) \[ S_4 = S'_4 + S''_4 \ll_E \frac{x}{L(x)} + \frac{x \log x}{L(x)^{1/57}} \ll \frac{x}{L(x)^{1/38}}. \]

The statement of Theorem 1.3 then follows from (5.1), (5.2), (5.5), and (5.6).

### 6 Proof of Theorem 1.5

First write

$$\pi_{E,b}^{\text{pseu}}(x) = \sum_{p \leq x \atop n_1(p) \text{ is pseudoprime to base } b} 1 \ll \sum_{n \leq 4x \atop n \text{ is pseudoprime to base } b} M_E(n).$$

By using the Cauchy–Schwarz inequality, it follows that

(6.1) \[ \pi_{E,b}^{\text{pseu}}(x) \ll \left( \pi_b^{\text{pseu}}(4x) \right)^{1/2} \left( \sum_{n \leq 4x} M_E(n)^2 \right)^{1/2}. \]

To bound the second sum on the right-hand side of (6.1), we use a result of Kowalski [12] who proved that for a curve $E$ with complex multiplication and for any $\varepsilon > 0$,

(6.2) \[ \sum_{n \leq 4x} M_E(n)^2 \ll \frac{x}{(\log x)^{1-\varepsilon}}. \]

We remark that in [12] there are no curves with complex multiplication defined over $\mathbb{Q}$ as the field of complex multiplication must be included in the field of definition of the elliptic curve. Then (6.2) is first proven for the sequence $\{n_F(p) = \#E(F_p)\}$ associated with $E$, where $p$ runs over the primes of the CM field [12, Theorem 5.4].

This first result can then be used to deduce the upper bound (6.2) by separating the rational primes into ordinary and supersingular primes of $E$, and by using [12, Theorem 5.4] to obtain (6.2) (see [12, Proposition 7.4]).

Theorem 1.5 then follows by replacing (6.2) and (1.6) in (6.1).
