(Received 11 August 2010; Accepted 24 November 2010; First published online 14 January 2011)

A consensus of expert opinion was used to provide both face and consensual validity to a list of potential indicators of sheep welfare. This approach was used as a first step in the identification of valid welfare indicators for sheep. The consensus methodology of the National Institute of Health, using pre-meeting consultation and focus group discussions, was used to ascertain the consensus opinion of a panel of sheep welfare experts. The Farm Animal Welfare Council’s five freedoms were used as a framework to organise a list of current on-farm welfare issues for sheep. The five freedoms were also the welfare criterion used to identify potential on-farm welfare indicators for sheep. As a result, experts identified 193 welfare issues for sheep and lambs managed on farms across England and Wales. Subsequently, a combination of animal-based (n = 52), resource-based (n = 13) and management-based (n = 22) welfare indicators was suggested for (i) adult rams, (ii) adult ewes (male and female sheep, over 1 year old), (iii) growing lambs (male and female sheep, over 6 weeks to 1 year old) and (iv) young lambs (male and female lambs, 6 weeks old and under). The results from this study could therefore be used to inform the further development of valid methods of assessing the on-farm welfare of sheep.

Keywords: sheep, animal welfare, indicator, expert opinion, validity

Implications

Valid welfare indicators are required nationally and internationally by farmers, veterinary surgeons, the sheep industry and farm inspectors in order to measure and monitor on-farm welfare standards for benchmarking, certification, farm assurance and legal purposes. Currently, on-farm welfare inspections rely on the assessment of management- and resource-based measures. However, there are increasing demands for measures that assess the quality of an animal’s life using direct animal-based outcomes. Compared to other farm animal species, few validated animal-based measures of sheep welfare currently exist. Therefore, this study has the potential to inform and enhance future on-farm assessments of sheep welfare.

Introduction

Consumer awareness and concern for farm animal welfare has provided the impetus for driving the provision of products from high welfare systems, assurance of farm animal welfare standards and demands for welfare labelling of food (Waiblinger et al., 2001; Blokhuis et al., 2003; Main et al., 2003b). In addition to non-regulatory purposes, welfare assessments are undertaken to assess compliance with legislative and regulatory standards (EFSA, 2007). Consequently, there is a need for valid, reliable and feasible measures for use in on-farm welfare assessment systems which would be transparent and fair to both producers and consumers (FAWC, 2009; Mullan et al., 2009).

In the past, on-farm welfare assessments focused on the evaluation of farm resources (e.g. provision of housing and feed) known as resource-based indicators or those that assess farmer policies and management practices (management-based indicators; Capdeville and Veissier, 2001; FAWC, 2009; Mullan et al., 2009). Since animal welfare can be considered to be the outcome of the interaction between genotype, management and the environment (Sørensen and Fraser, 2010), a valid assessment of welfare should also include animal-based welfare outcomes (FAWC, 2009; Mullan et al., 2009; Sørensen and Fraser, 2010).

A valid welfare indicator would be a genuine measure of animal welfare (EFSA, 2007; Bracke et al., 2008). Since
welfare measures (or indicators) are akin to diagnostic
tests, they may be evaluated in a similar manner. Essentially,
a new diagnostic test would be conferred as valid, if it pro-
duced the same result as an established reference test
(Greiner and Gardner, 2000). However, this approach is
problematic for animal welfare assessment as a reference
test does not currently exist (de Passille and Rushen, 2005).
An alternative approach is to use a consensus of expert
opinion to judge the validity of welfare indicators that are
incorporated into on-farm assessment protocols. By judging
the suitability and relevance of each measure, expert opinion
provides consensual and face validity to the selection of
welfare indicators (Abramson, 1974; Johnsen et al., 2001;
Scott et al., 2001; Bracke et al., 2002). Previously, expert
opinion has identified a number of welfare indicators for
cattle, poultry and pigs (Capdeville and Veissier, 2001; Whay
et al., 2003a; Botreau et al., 2009) and has also been used to
identify a number of welfare issues for sheep (Cronin et al.,
2002; Waterhouse et al., 2003; Pines et al., 2007; Phillips
et al., 2009).

The methods for gathering the consensus of expert
opinion vary, from using Delphi questionnaires (Whay et al.,
2003a; Phillips and Phillips, 2010), online surveys (Fernie
et al., 2008), small group meetings such as the Nominal
Group Technique (NGT; Delbecq et al., 1975) to conference-
style meetings (Glaser, 1980; NIH, 1990; Pines et al., 2007;
Rousling et al., 2007). The NIH consensus development pro-
gramme (NIH, 1990) is a well-recognised conference-style
method that has been used in human medicine to iden-
tify numerous clinical and biotechnological issues (www.
consensus.nih.gov). This method is relevant for develop-
mental research studies as experts meet face-to-face
enabling idea generation and open discussions (NIH, 1990).
The NIH approach can involve a pre-meeting consulta-
tion, such as the use of questionnaires to give experts greater
time to enlarge on the topic of interest (Glaser, 1980). In
addition, experts may be split into sub-groups during the
conference to allow an in-depth discussion of all the relevant
issues (Glaser, 1980).

The overall aim of this study was to establish valid,
reliable and feasible indicators for the on-farm assessment
of sheep welfare. This paper describes the initial identifica-
tion of a number of sheep welfare indicators which encum-
passed the welfare concepts in the Farm Animal Welfare
Council (FAWC) five freedoms (FAWC, 1994) and were sen-
sitive to the current on-farm welfare issues for sheep. An NIH
approach (NIH, 1990) allowed a panel of experts to judge the
validity (face and consensual) of sheep welfare indicators
that were included in on-farm assessment studies. Following
this initial validation step, the internal validity (evaluation of
bias, reliability and diagnostic accuracy) and the external
validity (generalisability, feasibility and applicability) of
these indicators would be evaluated in field studies (Greiner
and Gardner, 2000). Thereafter, the ranking or exclusion of
any indicators could be based on the evidence of their
diagnostic validity, reliability, and feasibility for use in on-farm
welfare applications.

Material and methods

Expert panel selection

The objective of the expert panel selection process was to
identify a broad panel of expert members (Garabed et al.,
2009). An ‘expert’ was defined as a person having a mini-
mum of 10 years sole experience of sheep farming in the UK
sheep industry and/or professional achievements in indus-
tries and organisations allied to sheep farming, veterinary
services and welfare research. Experts were short-listed by
members of the research team to avoid overlap in areas of
representation (Garabed et al., 2009). Following approval by
the Department for the Environment, Farming and Rural
Affairs (Defra), 33 experts were formally invited to attend a
1 day expert panel meeting.

Before their attendance, experts were given clear, written
guidance on the objectives of the meeting and the required
output of the expert panel – to produce a list of indicators of
sheep welfare, which encompassed all aspects of the five
freedoms and were sensitive to current on-farm welfare
issues for sheep in England and Wales. In addition, experts
were informed of their role at the meeting, that is, to validate
the identification of potential indicators of sheep welfare.
Where invited members did not respond to follow-up contact
(n = 2), or were unable to attend (n = 3), a substitute
member with similar expertise was selected from the short-
list and invited to attend. As a result, 33 members confirmed
their attendance.

Identifying on-farm welfare issues for sheep – postal
worksheet

One month before the meeting, a one-page worksheet was
distributed to all experts (electronic and postal hard copy) in
order to identify potential on-farm welfare issues for the
individual sheep. Each expert was asked to list a maximum
of 10 issues considered to affect the on-farm welfare of
(i) ewes (female sheep over 1 year old), (ii) rams (male sheep
over 1 year old), (iii) growing and fat lambs (any sex, over
6 weeks to 1 year old) and (iv) young lambs (from birth to 6
weeks old) in England and Wales. Experts were asked to
consider the factors that affected the welfare at the level of
the individual sheep. Anonymous responses from completed
worksheets were reviewed by the authors who categorised
the suggested welfare issues into the relevant area(s) of the
five freedoms framework (FAWC, 1994). The five freedoms
detailed by the FAWC are accepted as a sound framework for
the development of animal welfare indicators (Whay et al.,
2003a; FAWC, 2009). This information was summarised into
a document that was distributed in electronic and paper
versions to all panel members 1 week before the expert
panel meeting (Figure 1).

Identifying on-farm welfare issues for sheep – expert
panel meeting

The expert panel meeting was held on 23 February 2008, and
consisted of 30 members from welfare organisations and
charities (n = 2), sheep welfare research (n = 5), welfare
Figure 1 Flow-chart of the expert consensus of opinion method. Structure of the consensus of opinion methodology summarising the steps involved in the validation of the sheep welfare indicators. The final step in this flow-chart summarises the subsequent validation stages, in which the diagnostic and external validity of indicators are evaluated in on-farm studies.

Selection of expert panel members
- Defined expert criteria and informed invited experts of the role of panel and meeting objectives

Expert panel pre-meeting consultation
- Each expert asked to identify on-farm welfare issues for sheep and lambs using a postal worksheet
- Authors categorised suggested issues into the FAWC five freedoms
- A list of the suggested issues was distributed to all expert members ahead of the meeting

Expert panel meeting
- Meeting objectives and format of focus groups defined to the whole expert panel
- Authors presented current scientific knowledge regarding the on-farm welfare issues for sheep
- Focus group
  - Identified on-farm welfare issues for ewes
  - Identified on-farm welfare issues for rams
  - Identified on-farm welfare issues for growing lambs
  - Identified on-farm welfare issues for young lambs

Scientific presentation to panel
- Author presented current scientific literature regarding development of animal welfare indicators
- Focus group
  - Identified indicators for ewes
  - Identified indicators for rams
  - Identified indicators for growing lambs
  - Identified indicators for young lambs

Presentation of focus group outputs
- Facilitators presented the list of indicators identified by each focus group to the whole panel
- Open discussion between all members of the expert panel

Post-meeting distribution of consensus output
- List of indicators identified by all focus groups distributed to all experts following the meeting
- Experts agreed on the final consensus output providing validity (face and consensual) to the identified indicators

On-farm validation of indicators
- Evaluation of the diagnostic and external validity of indicators

Identifying potential welfare indicators – expert panel meeting
The next stage in the expert panel process was to identify valid indicators of sheep welfare based on the suggested welfare issues for sheep and the five freedoms framework (FAWC, 1994). Following the NIH process (NIH, 1990), the authors gave a presentation to the panel on the current

inspectors (n = 1), veterinary animal welfare advisors (n = 2), government advisors on animal welfare policies (n = 2), veterinary sheep specialists (n = 3), veterinary surgeons from general practice (n = 4), sheep farmers (n = 5), sheep industry services (n = 2), and sheep production consultants (n = 4). The meeting followed NIH guidelines (NIH, 1990), in which an introductory presentation on the objectives of the research project was given and members were informed of their specific role in the validation of welfare indicators. The expert panel comprised of members with different experiences and expertise in sheep health, welfare and production. Therefore, in line with NIH meetings (NIH, 1990), the authors gave the expert panel a presentation on the current, scientific knowledge of on-farm welfare issues for sheep (Figure 1), identified through a systematic literature search (C. Phythian, 2008, unpublished). For the purposes of this study, welfare was defined as a factor, event or action that affected one or more of the five freedoms of an individual sheep (FAWC, 1994). The panel was then divided into four focus groups (Figure 1). Each group focused on identifying the welfare issues for one of four production stages: (i) ewes, (ii) rams, (iii) growing and fat lambs and (iv) young lambs. The aim was to allow a balance of opinions within each group and a mix of members from the different representative areas was allocated into each group. A focus group comprised of seven or eight experts, plus a facilitator, who was a trained member of the project team (Glaser, 1980; Krueger and Casey, 2009). In addition, two non-participating recorders maintained accurate written minutes of group discussions. The welfare issues document, which categorised all the welfare issues identified from the pre-meeting worksheet into the five freedoms framework (FAWC, 1994), was distributed to the panel 1 week ahead of the expert panel meeting. This provided the experts with more time to consider the welfare issues. At the meeting, this document was used as the basis for focus group discussions. All panel members were given the opportunity to consider, discuss, modify and clarify the welfare issues listed in this document and were free to alter the categorisation of any welfare issue within the five freedoms framework. As well as guiding the identification of welfare indicators by the experts, this document was also one of the final outputs of the expert panel meeting – akin to the consensus of expert opinion statement produced in NIH conferences (NIH, 1990).
scientific knowledge of animal welfare indicators, including those developed for other species. Experts then returned to their focus groups (Figure 1) and were asked to consider and identify measures capable of assessing each of the issues listed within the five freedoms framework. Experts were asked to identify indicators that were animal-based (where possible), non-invasive and practicable for assessments performed under farm conditions. Once the focus groups had completed this task, the panel reconvened and each facilitator gave a presentation on the valid indicators identified by their group. All members of the panel were then asked to comment on the output of the other focus groups. Following the guidance of NIH consensus methods, an official output for the consensus of expert opinion was produced by the authors after the meeting (NIH, 1990). This consisted of a final document listing the on-farm welfare issues and indicators for sheep as suggested by the expert panel. This document was electronically distributed to all experts within 1 week of the meeting. Experts were then requested to read the document and confirm that the indicators and issues were those as suggested at the meeting. If the majority of experts agreed with the meeting outputs, then a consensus of opinion would be established (NIH, 1990).

Results

On-farm welfare issues for sheep

A total of 19 out of 33 worksheet responses was received (response rate of 58%). Experts suggested 193 potential welfare issues for sheep in England and Wales. Of these, 53 on-farm welfare concerns were identified for the ewe production stage. A total of 45 issues for rams, 53 issues for growing and fat lambs and 42 issues for young lambs were also raised. Table 1 lists the welfare issues identified in the postal worksheet by at least 50% of experts (n = 17). The pre-meeting consultation found that lameness was consistently identified as an on-farm welfare issue for all four of the production stages. For young lambs, mutilation procedures of tail docking and castration were considered to be key welfare issues (Table 1). Poor body condition was identified as an on-farm welfare issue for both ewes and rams, whereas gastrointestinal parasitism of growing lambs and dystocia in ewes were issues specific to these production stages.

At the panel meeting, experts identified and categorised a total of 193 welfare issues for ewes, rams and lambs into the relevant criteria of the five freedoms framework (FAWC, 1994). Since all the experts indicated their agreement with the post-meeting output documents, a consensus of expert opinion on the welfare issues for sheep was achieved.

Given the large number of issues identified by the panel, a summary of the welfare issues identified for each freedom criteria was produced (Table 2). The authors grouped and summarised the 193 issues into a list of general welfare issues, which covered all four production stages (n = 58). Where appropriate, issues specific to the welfare of ewes, rams, young and growing lambs were highlighted. This organisation provided 14 general welfare issues within the freedom from hunger and thirst, 14 within the freedom from discomfort, 11 within the freedom from pain, injury and disease, 8 for freedom to express normal behaviour and 10 general welfare issues were produced under the freedom from fear and distress criterion. For example, within the freedom from pain, injury or disease, the expert panel suggested that a large number of diseases and health conditions were on-farm welfare issues for sheep and lambs. Accordingly, specific diseases and health conditions were grouped and summarised by the authors, for example, contagious ovine digital dermatitis, foot rot and scald were summarised as ‘infectious foot lesions’ (shown in brackets in Table 2). Subsequently, the general disease conditions were grouped into an overall, general welfare issue, which was termed ‘heath status’ (Table 2).

On-farm welfare indicators for sheep

The animal-, resource- and management-based indicators suggested by the panel are shown in Table 3. Of the animal-based indicators suggested, 10 were identified for ewes, 13 for rams, 11 for young lambs and 9 for growing and fat lambs. Many of the welfare indicators identified for each production stage were similar. Since there was overlap across the focus group outputs, the authors grouped all the suggested measures into a single list of animal- (n = 26), resource- (n = 13) and management-based (n = 22) indicators (Table 3). Although most indicators could be used to assess all four production stages, the assessment of time taken to stand and suck, along with an overall indicator of lamb thrift was specifically suggested for young lambs. Resource- and management-based indicators suggested by the four focus groups also showed similarity, so these indicators were also grouped into a single list (Table 3). Resource-based measures included the assessment of housing and

|                                         | disease prevention and control (vaccination, anthelmintic control, appropriate action and treatment of disease, stockperson inspection, veterinary input, culling policy, bio-security measures)                                                                                                           |
| Freedom to express normal behaviour     | appropriate intervention at lambing\(\text{YL}\) reproductive management practices (use of artificial insemination) space allowance: opportunity for exercise for indoor-housed animals provision of environmental enrichment for housed animals group size and composition (overcrowding, mixing unfamiliar sheep)
|                                         | isolation of individual sheep (sick animals) artificial rearing of lambs\(\text{YL}\) maternal behaviour (ewe-lamb bonding, mis-mothering)\(\text{YL}\) artificial insemination intensive finishing systems\(\text{GL}\)
| Freedom from fear and distress          | appropriate intervention at lambing\(\text{YL}\) artificial insemination intensive finishing systems\(\text{GL}\) quality of handling: stockperson skills and quality of handling facilities method and timing of weaning
associated facilities and provisions, for example, space allowance and quality of bedding. The panel identified that castration and tail docking procedures were painful procedures (Tables 1 and 2). However, experts suggested that it may be more feasible to ascertain whether these mutilations were practised, the method used, and the on-farm policy regarding analgesia and anaesthesia use, rather than measuring the pain responses of lambs (Molony and Kent, 1997).

Experts were also asked to consider the feasibility of any suggested measures (Table 3). Assessments under working farm conditions were considered to pose several difficulties, including the location and gathering of extensive flocks, handling of pregnant ewes and gathering of ewes with lambs at foot. Experts therefore suggested that the nature of the sheep production year should be considered before assessment visits were undertaken. Following distribution of the post-meeting document, two panel members made additional comments, which were duly noted and recorded. These comments did not affect the list of identified indicators (Table 3), but they helped to inform the on-farm evaluation studies. Experts confirmed the validity of the indicators listed in the post-meeting consensus document. Therefore, a consensus of expert opinion provided validity to the selection of welfare indicators to undergo on-farm testing on sheep in England and Wales.

Discussion

Expert validation of welfare indicators

In the absence of a reference test (or gold standard) for welfare assessment (de Passillé and Ruschen, 2005), previous welfare research has also based the selection and initial validation of welfare indicators on expert opinion (Cronin et al., 2002; Whay et al., 2003a; Bracke et al., 2008). This is because expert opinion is considered to provide both face and consensual validity to the welfare indicators (Abramson, 1974; Johnsen et al., 2001; Scott et al., 2001). The study presented here is the first to determine valid sheep welfare indicators for the on-farm welfare assessment of sheep using an NIH consensus approach (NIH, 1990). The NIH methodology provided validation of welfare indicators that were identified by expert opinion. The consensus method appears to be suitable for other animal health and welfare research applications, for example, agreeing on standard laboratory techniques or defining a specific animal welfare condition. Before applying this method, there are several factors that need to be considered. First, the definition of who is an ‘expert’ and what is their level of expertise (Spoolder et al., 2003). Second, expert opinion can differ according to occupation (Bracke et al., 2008; Fernie et al., 2008). Therefore, a biased view of welfare may be ascertained by using an unbalanced panel with experts from specific occupations (Vang, 1986). Furthermore, consensus methodologies make assumptions on the quality of the expert panel’s decisions (Fink et al., 1984). Expert opinion may have little in common with widely known scientific facts or reasoning (Vang, 1986) and specialists may concentrate on a small and specific issue instead of considering the whole picture (Vang, 1986). Expert opinion should alter as scientific knowledge advances, although experts can ignore welfare research findings and provide opinion based solely on their personal experiences (Main et al., 2003a). In view of these issues and in the absence of a reference test for animal welfare, a combined approach using a scientific literature review (C. Phythian, 2008 unpublished) and expert opinion guided the identification of valid welfare indicators in this study (Figure 1). The advantage of employing expert opinion, over the opinion of the study researchers, is that a group of experts would be expected to possess greater diversity in experience and knowledge of the subject under discussion, which is beneficial to an idea-generation process. As a number of concerns are recognised with the use of expert opinion, these factors were accounted for in both study design and conduct. In particular, the following considerations were made: (i) clear definition of experts (Garabed et al., 2009), (ii) selection of experts according to level of expertise, (iii) balanced composition of members in terms of expertise in sheep welfare and occupation, (iv) quality of decisions, by using a sound consensus method (NIH, 1990), (v) clear communication of meeting objectives and fulfilment of distinct tasks (Kynn, 2008) and (vi) presentation of scientific knowledge to establish an educated and informed panel.

Methods for gathering a consensus of opinion

The Delphi method has been suggested as a feasible way of collecting expert opinion by avoiding conflicts between individual opinions and thereby minimising bias of opinion (Delbecq et al., 1975; Whay et al., 2003a). However, Delphi questionnaires can be criticised on the grounds of poor response rates and long response times (Hsu and Sanford, 2007). Furthermore, postal questionnaire methods are unsuitable for research requiring personal and direct communications (Fink et al., 1984). Here, face-to-face Delphi questionnaire methods, recently used to identify individual farmer concerns for sheep welfare (Phillips and Phillips, 2010) may prove useful. Individual interviews were not considered to be appropriate for this study, instead, a method that elicited the opinion of a number of experts during a 1-day meeting and encouraged discussion and ideas-generation was required. As a result, other face-to-face consensus methods including the NGT (Delbecq et al., 1975), Improved Nominal Group Technique (Fox, 1989) and the NIH method (NIH, 1990) were examined. The selected NIH method allows researchers to present the most current, scientific knowledge and concepts to experts attending a consensus-style meeting (NIH, 1990). NIH can include a pre-meeting consultation to prevent a ‘bottleneck’ in group discussions and also to reduce the meeting time required (Fox, 1989). Focus groups, as used in NIH meetings, allow for idea generation and exchange of expertise and opinions (Glaser, 1980; Fitzpatrick and Boulton, 1994; Krueger and Casey, 2009). In this study, each focus group was comprised of seven to eight members, guided by trained facilitators (Glaser, 1980) to encourage full contribution and minimise over-domination by any member (Delbecq et al., 1975; Krueger and Casey, 2009). To reduce opinion biases, groups were mixed in terms of occupation, experience and expertise, and this also prevented the group from referring to the opinion of any one individual (Kynn, 2008; Krueger and Casey, 2009). There is a lack of a definition on the establishment of a consensus in decision-making processes (Scott and Black, 1991). The NIH method, takes the ‘majority rule’ approach (NIH, 1990) to the identification of consensus, so, one disadvantage is that minority or extreme views may be ignored. The goal of this study was to identify broad expert agreement, so it may be appropriate to discount very polarised or minority opinions (Scott and Black, 1991). The final step in NIH methods allows experts to comment and deliberate on the scientific evidence before finally offering their judgement (NIH, 1990). The post-meeting distribution of the output of this study (Figure 1) permitted individual experts to review the welfare indicators further and confirm to the authors their agreement of the list of welfare indicators as created at the expert panel meeting. As a result, this approach provided both face and consensual validity to the sheep welfare indicators identified by the expert panel (Table 3).

Welfare issues identified

This study identified a number of on-farm welfare issues affecting sheep. Although experts were asked to specifically identify issues that were relevant to farms in England and
Wales, many of the welfare issues raised are applicable to other countries, systems and stages of production, such as transport and lairage (Cronin et al., 2002; Waterhouse et al., 2003; Phillips and Phillips, 2010). Furthermore, to the author’s knowledge, this is the first study to validate potential welfare indicators that consider: (i) sheep of all ages (neonates to adult sheep), (ii) all stages of on-farm production (birth, lactation, weaning, growth, reproduction) and (iii) the diversity in sheep management (intensive, indoor-managed flocks to large extensive systems). The pre-meeting worksheet identified thin ewes (84% of respondents), hypothermia of young lambs and endo-parasitism of growing lambs (74%) were on-farm welfare issues. Pre-meeting consultation also found that both lameness and poor body condition were consistently identified as sheep welfare issues (Table 1). Interestingly, the welfare issues suggested by this expert panel concur with the expert opinion regarding the welfare issues for extensively managed sheep (Waterhouse et al., 2003), and for sheep managed in Australia (Cronin et al., 2002; Phillips et al., 2009; Phillips and Phillips, 2010). In contrast to other studies (Cronin et al., 2002; Rousing et al., 2007; Phillips et al., 2009; Phillips and Phillips, 2010), the suggested welfare issues were not ranked in terms of their importance. Ranking can be used to create an overall welfare index (Fernie et al., 2008), or to identify a set number of measures that are used to assess on-farm welfare standards (Rousing et al., 2007). However, the creation of an overall welfare index or overall welfare assessment system for sheep was not the objective of this study. Instead, the aim was to identify a number of valid welfare measures, essentially individual diagnostic tests, which would undergo further validation in on-farm studies. A fundamental aspect of this study was to view welfare from the animal’s point of view by encompassing both physical and mental elements as detailed in the FAWC five freedoms (1994). As the authors consider that each of the five freedoms is important to the welfare of the individual sheep, ranking was not appropriate for this initial study stage. Indeed, ranking of measures at this stage risked omitting a welfare issue that was specific to a certain time point or to a particular farm management system. The authors intended that any ranking, synthesis or exclusion of the suggested indicators would be based on the results of diagnostic validity, reliability and feasibility studies (Figure 1).

**Potential sheep welfare indicators**

Before this study, indicators for the on-farm assessment of sheep in England and Wales had not been identified. Previous work has identified potential animal-based welfare indicators for sheep transported by sea (Pines et al., 2007) and for organic sheep managed in Italy (Napolitano et al., 2009). Animal-based indicators have received increasing attention for their value in on-farm welfare assessments (Whay et al., 2003b; Knierim and Winckler, 2009; Mullan et al., 2009). A combination of animal-, resource- and management-based indicators may be most appropriate for on-farm welfare assessments (Capdeville and Veissier, 2001; Waiblinger et al., 2001). The panel therefore generated a range of animal-based, resource-based and management-based indicators that they considered to be practical given on-farm assessment conditions and the limits of a 1-day assessment period (Table 3).

**Animal-based indicators.** Many of the animal-based indicators suggested by this expert panel were focused on measures of flock health, for example, body condition scoring (BCS), lameness scoring, and skin lesion assessment. Although BCS was identified as a useful welfare assessment tool, and has been scientifically validated as a measure of the body fat content of sheep (Russel et al., 1969), the panel recognised that BCS was not an inappropriate indicator for young and growing animals. The panel also suggested that fewer categories of condition scores may be more appropriate for welfare assessment purposes. For example, sheep could be categorised as simply ‘fit’, ‘fat’ or ‘thin’. Another specific indicator suggested by the panel included the use of an overall young lamb thriving score in order to categorise lambs as either ‘thriving’ or ‘ill-thriven’. This composite indicator was designed by the panel members to provide an overall welfare score based on the assessment of a number of health and welfare measures such as posture, demeanour, standing ability and also specific health-based measures such as abdominal fill, gait, body condition and the presence of any ocular abnormalities. Experts also identified the need to assess animals managed at specific times during the sheep production calendar. They also emphasised the importance of including artificially reared lambs in any young lamb welfare assessments.

Experts suggested that an assessment of sheep behaviour was a useful welfare assessment tool and that behavioural separation of individual animals from the flock and/or the expression of a dull, depressed demeanour clearly indicated a health and/or welfare issue for the individual sheep. In addition, the use of a whole-animal behavioural approach to sheep welfare assessment was proposed. The expert panel identified that qualitative behavioural assessment; a holistic approach to the assessment of animal behavioural expression (Wemelsfelder and Lawrence, 2001), should also be included in the list of animal-based indicators (Table 3).

Overall, the panel’s suggestions closely followed those of another expert panel (Waterhouse et al., 2003) who proposed that on-farm issues for sheep welfare may be considered in terms of the severity, duration and intensity of the effect on welfare. In this project, the intensity was considered to be the number of sheep affected by a specific indicator. There is a lack of definition between individual and flock welfare indicators (Waterhouse et al., 2003), but in this study, experts were asked to consider welfare issues that were important for the individual sheep. Although it was clear from the outputs of each focus group that experts identified issues and indicators that were relevant to the welfare of the individual sheep, they suggested that the interpretation of indicator assessments could be based on a flock-level approach. Indeed, the panel in this study suggested that the flock prevalence of indicators was the most valid and feasible way of performing on-farm assessments of...
the animal-based indicators. Experts were informed that any indicators initially suggested by the panel would undergo further validation in the next stage of the project, when diagnostic test evaluation of the indicators would be performed in field studies. This approach permitted the study of both individual and group-level methods of assessing sheep. Results of on-farm testing of indicators would be presented to the expert panel at subsequent meetings in order to allow experts to make an informed and science-based decision on the interpretation of individual- and flock-based welfare assessments. The panel also suggested that, where appropriate, the severity and duration of the welfare indicators could be considered in any scoring systems that were developed by the authors.

As this is the first step in identifying valid indicators of sheep welfare, not all the animal-based indicators suggested by the panel may be applied during field testing. Experts suggested that biochemical measures (Table 3), such as plasma cortisol, could be used for on-farm assessment of sheep welfare, although they also suggested that measures may not be feasible for a whole flock assessment. Interestingly, experts did not suggest any non-invasive biochemical measures such as faecal cortisol levels. Accordingly, the authors did not incorporate any biochemical measures into the field testing of indicators.

Resource- and management-based indicators. The indicators suggested by the panel (Table 3) broadly fell into (i) assessments of grazing, housing and on-farm facilities, (ii) assessments of farm records, and, finally, (iii) discussions with farmers to ascertain on-farm management practices. The effect of season and production system should be considered in the application of resource-based indicators, for example, sheep may only be housed during short and specific periods and often receive intermittent supplementary feeding. For a large proportion of the sheep production calendar, the main resource for sheep in the United Kingdom may be considered to be the provision of grazing. Therefore, resource-based assessments would be likely to be focused on the quality and the quantity (sward height) provided (Table 3).

Conclusion

The objective of this study was to identify valid indicators for the on-farm assessment of sheep welfare. This study followed good practice guidelines regarding meeting design, conduct of focus groups, and selection of experts in order to use a consensus of expert opinion to validate potential indicators of sheep welfare. Although the NIH approach is widely used in human medicine, it has not previously been reported for use in expert consultation processes for animal health and welfare research purposes. A clear advantage for expert consultations that require direct and face-to-face communication of a number of members is the balanced, multi-disciplinary, science-based and informed approach offered by the NIH technique. Experts identified a large number of on-farm welfare concerns for sheep and also suggested a range of potential animal-, resource- and management-based indicators. The use of the method employed here may be appropriate for the development of welfare indicators for other species. This expert validation process was the first step in the identification of valid indicators of sheep welfare. The next step is to investigate the diagnostic validity (accuracy and reliability) and feasibility of these measures during field studies.

Acknowledgements

The authors gratefully acknowledge the role of Defra in funding this project (AW1025, Development of indicators for the on-farm assessment of sheep welfare) and thank all members of the expert panel for their contribution and support with the project.
