**Learning Objectives:** To illustrate the anatomy of the middle ear ventilation routes to the attic, to understand the pathophysiology that leads to aditus block syndrome and to show how to functionally restore the blocked pathways of ventilation.

**Introduction:** This narrated video demonstrates the surgical principles of the combined endoscopic and microscopic approach for an extensive epitympanic cholesteatoma with mastoid extension.

**Methods:** A pre-operative endoscopic exam and a CT scan of the temporal bone were obtained for surgical planning. The endoscopic portion of the surgery was performed with rigid 0, 30 and 45 degree endoscopes, 3 mm in diameter and 14 cm in length, connected to a three chip video camera and high definition monitor. A microscopic mastoidectomy was performed to remove disease in the mastoid antrum.

**Results:** Cholesteatoma was removed in its entirety through a combined endoscopic and microscopic approach. The cholesteatoma extended medially to the ossicular chain and the head of malleus and incus were removed. Ossicular chain reconstruction was performed with autologous incus. The atticotomy defect was reconstructed with a composite graft of conchal cartilage and perichondrium. The patient was free of disease at second look transcanal endoscopic surgery with excellent hearing result.

**Conclusions:** Endoscopic ear surgery offers wide field visualization of the attic space and the mastoid antrum. When cholesteatoma has extension into the mastoid space posteriorly to the point of reach of the endoscopic technique, a microscopic mastoidectomy is required for complete eradication of mastoid disease. This surgical case demonstrates how the endoscopic and microscopic surgical approach to cholesteatomas are not exclusive of each other but they can be utilized in combination to fully visualize and remove extensive disease.
Learning Objectives:

Objective: To report a case of idiopathic oculostapedial synkinesis without facial nerve disorder.

Patient: A 30-year-old woman with tinnitus synchronous with eye closure is presented. The patient had no history of facial nerve disorder.

Result: An impedance audiometer, in the absence of an auditory stimulus, was used to record tympanic membrane compliance without sound stimulation, revealing decreased compliance in the concomitant with eye blinking. Her symptoms disappeared spontaneously, so no intervention was undertaken.

Conclusion: Although oculostapedial synkinesis is often observed as one of the sequelae of facial nerve palsy, idiopathic oculostapedial synkinesis is very rare. The use of an impedance audiometer in the absence of an auditory stimulus is very useful for demonstrating objective changes in the compliance of the tympanic membrane. It is assumed that the cause of the synkinesis in our case was abnormal transmission of signals for orbicularis oculi muscle to the stapedial and orbicularis oris muscles rather than misdirected regenerating fibers. Resection of the stapedial muscle tendon should be considered if her symptoms recur.

Factors influencing the decision-making of cochlear implantation in congenital hearing loss: A retrospective cohort study

Presenting Author: Takashi Fujiwara
Takashi Fujiwara
Kurashiki Central Hospital

Learning Objectives:

Background / Objective: Cochlear implantations (CIs) are well recognized and accepted treatment for severe to profound congenital hearing loss, but CIs are not performed because of malformation, family attitude and others. We conducted retrospective chart review to examine the clinical factors influencing the decision making of CIs in congenital hearing loss.

Study Design: Retrospective chart review.

Methods: We included bilateral congenital hearing loss children who first visited Ehime Welfare Center for the Handicapped from April 2007 to December 2015, and met the criteria of the indication for CIs. To examine factors associated with opt-out cochlear implantation, we performed univariate analyzes of following factors; age, sex, birth weight, maternal age, cochlear malformation, multiple organ abnormalities, severe handicap, deaf family and availability of CI-rehabilitation service.

Results: During the study period, 38 bilateral congenital hearing loss children met the criteria for cochlear implantation. Of 38 children, 10 children were unwilling to use CIs. In univariate analysis, severe handicap and deaf family are correlate with opt-out CIs.

Learning Objectives:

Introduction: Magnetic resonance imaging (MRI) is becoming increasingly used as a tool for cholesteatoma diagnosis. The purpose of this retrospective study was to assess a role of T1 weighted imaging (T1WI) in diagnosing recurrent temporal bone cholesteatoma with Diffusion-weighted MR imaging (DWI).

Method: We studied 44 patients (45 temporal bones) with preoperatively suspected cholesteatoma. Each patient underwent an MRI examination including both DWI and T1WI. Diagnosis of cholesteatoma was based on the evidence of a high intense image on DWI. Results of MRI were compared with operative diagnosis.

Result: The patients were consisted of 24 males and 20 females, ranging in age between 8 and 87 (median age = 53). DWI accurately predicted the presence of cholesteatoma in 31 of 36 cases, and it correctly excluded in 5 of 9 cases. False positives included 2 cholesterol granulomas, 1 schwannoma, and 1 fibrosis. False negatives included 4 small keratin pearls, 1 wetter debris caused by infections. Overall sensitivity and specificity for detection of cholesteatoma were 86.1% and 55.6%, respectively. Positive predictive value and negative predictive value were 88.6% and 50.0%, respectively. Overall accuracy for detection of cholesteatoma was 80.0%. Only 5.6% of cholesteatomas (2/36) showed high intensity on T1WI, on the other hand, 75.0% of false positives (3/4) showed high intensity on T1WI. When diagnosis of cholesteatoma was based on the evidence of both high intensity on DWI and low or intermediate intensity on T1WI, overall accuracy for detection of cholesteatoma increased to 82.2%.

Conclusion: The combination of DWI and T1WI may improve specificity and overall accuracy for detection of cholesteatoma.
