antipsychotic medications are effective and recommended treatment for active psychotic symptoms, though there is not so much evidence for the long term (i.e. several years of antipsychotic treatments). Additionally, the clinical use of these medications is not always straightforward because of their known side-effects and the fact that, in all psychiatric disorders and other illnesses in medicine, there are always patients who do not want to take the recommended treatment. This seems to have been the case in the trial pointed out by Bindman & Kripalani. When considering the long-term effects of antipsychotics, it is evident that the long-term treatment of psychosis needs to be developed further.

We agree that it would be dangerous to see different treatments as alternatives to each other, and it has been shown that in psychiatry a combination of different treatments is, in general, more effective than any of them alone. Psychotherapy in the early phase of illness could be effective not only in preventing psychosis at prodromal phase, but also in enhancing adherence to antipsychotic medication. Current treatment guidelines do not suggest that treatment of first-episode psychosis should include only antipsychotic medication without psycho-social treatment, but rather state that medication is one of the cornerstones of psychosis treatment. We believe there is still a lot to do in developing both medication and psychosocial treatments for schizophrenia, and hopefully active research can support this development.

Tully and colleagues justify the introduction of electronic monitoring of medium secure patients without indication of the size of the problem of abscording or the incidence of serious harm other than to reference an article in *The Sun* newspaper, which is neither informative nor free of bias.

Decisions around leave for patients detained within a medium secure unit are clearly complex. Consideration should always be given to the risk of abscording and associated risks if the patient were to abscond. Thus, patients who are at high risk of abscording and a serious risk to the public would not receive leave, whether they were tagged or not. Another factor is the clinical team’s trust in that patient to use leave appropriately. Tagging patients would be a very clear indicator of a lack of such trust.

The suggestion that patients enter into electronic monitoring with consent is questionable: many patients in our experience abide by suggestions of their clinical team in order to progress through the system. Given that there is yet to be a strong argument that tagging is necessary and primarily in the patient’s best interest (as opposed to a matter of public protection), can one justify this coercion? We would be very interested to know the process in which patients’ perspectives were taken into account and whether this has altered the intervention.

Electronic monitoring would inform the clinical team if the patient were to breach the conditions of their leave in terms of approximate location and time of leave; however, it would not inform the team as to what that patient was doing with their leave and would not necessarily prevent serious incidents occurring, as...
suggested. The use of a device whose main purpose has been pioneered by the criminal justice system seems to take us closer to making our hospitals prisons. A recent report published by the Criminal Justice Joint Inspection reiterates their 2008 findings that enforcement thresholds were not sufficiently stringent. With notable problems implementing this system within the criminal justice system, is it justifiable to implement it within the forensic services, given the cost of such a system?

Given the recent concerns about certain international security companies, the provision of such tags also raises ethical issues. Confidentiality must also be considered – would said companies have access to patient names and locations? The comparison of electronic monitoring with other uses of technology within psychiatry, such as mood monitoring via text message, is bizarre. The principles approach gives us a framework in terms of judging whether an intervention respects autonomy, beneficence, non-maleficence and justice. Debate of these principles will exceed the remit of this letter; however, it is worthwhile considering autonomy and beneficence in particular relating to the patient: we suggest that there is a breach in both. The weighing of these principles will not be easy and it will be a matter of debate whether the principle of justice will outbalance the former.

As the authors state, robust research in this area is needed and we look forward to reviewing the evidence.

3 Shaw D. Satellites used to track mentally-ill violent criminals. BBC News, 25 August 2010.

Authors’ reply: We had hoped that our article would stimulate a balanced discussion about this complex issue. We entirely agree with the view expressed in both letters that trust and therapeutic alliance between the patient and the treating team are critical components of the recovery process. We do not believe, however, that use of electronic monitoring necessarily indicates a lack of trust. It was envisioned that the device be used primarily for patients in the initial stages of taking leave as part of their clinical pathway towards discharge into the community. Our clinical experience, supported by as yet unpublished data, confirms that this has been the case in our service. In these circumstances, electronic monitoring may even help to further develop a trusting relationship between the wearer and the team, by granting earlier and more frequent leave and by allowing the patient to demonstrate avoidance of exclusion zones when on unescorted leave. There must be a balance between trust and therapeutic optimism in our treatment of our patients. Furthermore, viewing trust as being simply ‘present’ or ‘absent’ would be a naïve approach in forensic services. These questions are being explored in quantitative and qualitative research of electronic monitoring in our service.

Both letters raise concerns about granting of leave for high-risk patients. Watson et al point out that decisions surrounding leave are complex, a view that we share. However, the implied view in both letters that patients can be discretely classified into high risk for absconding or not is again overly simplistic. Clinical impression alone in risk assessment has been shown to be unreliable and validated risk assessment tools have been shown to be more useful in identifying individuals at low rather than high risk. No validated tool for the assessment of absconding risk yet exists, though we are currently working on developing one. Risk management, therefore, involves a component of positive risk-taking aided by creative management strategies. We propose that electronic monitoring is such a strategy.

Watson et al are liberal in their use of the term ‘coercion’. A policy was put in place whereby patients were informed that use of electronic monitoring was optional and if they chose to decline to wear the device, their leave would be risk assessed as per normal procedure. Consent is another complex issue in psychiatry and can be defined in degrees, rather than as a binary concept. It is true that patients’ decisions about consent to electronic monitoring are likely to be influenced by their wish to move more quickly towards leave and discharge. This has parallels with consent to medication and engagement in psychotherapies and occupational activities, particularly in the forensic setting.

Watson et al express concern about forensic services being closely aligned with the prison system. We believe that the use of secure units with locked wards and secure perimeters represents a level of coercion much more closely aligned to this system than does electronic monitoring. Any strategy that can help minimise the amount of time spent in such units would then surely be a welcome development for those concerned about patient liberty and overall progress. Far from making our units more like prisons, one of the key aims of our strategy was to allow for engagement in community leave and activities at the earliest possible stage. As Simpson & Penney point out, electronic monitoring may allow the person more apparent personal freedom than their clinical risk would otherwise allow.

The article referenced in The Sun was chosen as an example of media coverage of such absconding events. That such reports are often sensationalised or biased is one of the many challenges facing mental health services and patients. Media coverage of absconding events leads to reputational damage for services and can undermine the confidence of the community. We cannot and should not ignore community attitudes towards system breaches, especially as clinicians will be held to account when they occur. Another of our aims is therefore to reduce the frequency of these incidents, for the protection of the public and the reputation of our service.

Watson et al are correct in saying that electronic monitoring cannot directly prevent violent incidents. We believed that this was self-evident and therefore we did not address this issue in our article. Regarding costs, a cost–benefit analysis is currently underway. As our article states, our service was acutely aware of the important ethical considerations and we sought legal and ethical advice. A commentary addressing legal and ethical issues in more depth is currently being prepared. The questions Simpson & Penney raise about reoffending, recovery and longer-term outcomes are valid and we hope to address these in our future research.
