On number fields with given ramification

Gaëtan Chenevier

Abstract

Let $E$ be a CM number field and let $S$ be a finite set of primes of $E$ containing the primes dividing a given prime number $l$ and another prime $u$ split above the maximal totally real subfield of $E$. If $E_S$ denotes a maximal algebraic extension of $E$ which is unramified outside $S$, we show that the natural maps $Gal(\overline{E_u}/E_u) \rightarrow Gal(E_S/E)$ are injective. We discuss generalizations of this result.

1. Introduction

Let $E$ be a number field and $S$ a nonempty set of places of $E$. We denote by $E_S$ a maximal algebraic extension of $E$ unramified outside $S$. Let us fix $u \in S$ and an $E$-embedding $\varphi$ of $E_S$ in an algebraic closure $\overline{E_u}$ of $E_u$. In this paper, we are interested in the following property:

$$E_S \text{ is dense in } \overline{E_u}, \quad (P_{E,S,u})$$

where the identification of $E_S$ with $\varphi(E_S)$ is understood. It is easy to see that $P_{E,S,u}$ is independent of the choice of $\varphi$, and equivalent to each of the following properties:

(i) the map $Gal(\overline{E_u}/E_u) \rightarrow Gal(E_S/E)$ induced by $\varphi$ is injective;

(ii) the $E_u$-vector space generated by $E_S$ is $\overline{E_u}$;

(iii) for all finite extension $K/E_u$, there exists a number field $E'/E$ unramified outside $S$ and a place $u'|u$ such that $K$ has a continuous embedding into $E'_u$.

A trivial remark is that if $u \in S' \subset S$, then $P_{E,S',u}$ implies $P_{E,S,u}$. Moreover, a simple argument using Krashner’s lemma and a weak approximation theorem shows that a stronger form of $(P_{E,S,u})$ is true\(^1\) if $S$ contains almost all of the places of $E$. However, Minkowski’s theorem asserts that $Q_{\{\infty\}} = Q$, hence $P_{Q,\{\infty\},\infty}$ is not satisfied. For these reasons and others related to arithmetic geometry which will become clear later, we focus our attention on the case where $S$ is a finite set containing all of the archimedean places of $E$ and all of the finite places dividing a given prime number $l$. As $P_{E,S,u}$ is then obviously true for each archimedean place $u$ (e.g. because of cyclotomic fields), let us assume also that $u$ is finite. At least in this setting, the question of

---

\(^1\)Let $M$ be a local field, $d \geq 1$ an integer, and $Q \in M[T]_d$ a separable polynomial of degree $d$. By continuity of roots and Krashner’s lemma, if $R \in M[T]_d$ is sufficiently close to $Q$, then $M[T]/(R) \simeq M[T]/(Q)$ as $M$-algebra. Now, let $S'$ be a finite set of places of a number field $E$, and let us fix for each $x \in S'$ an étale $E_x$-algebra $A_x$, each of same degree $d$. Then the argument above, the primitive element theorem, and the weak approximation for the affine line over $E$, show that there exists an étale $E$-algebra $A$ of degree $d$, with $A \otimes E_x \simeq A_x$ for all $x \in S'$. It implies the claim if we take $S'$ to be the set of places $x$ of $E$ such that $x = u$ or $x \notin S$. $A_u := K$, and (for example...) $A_x = E'_x$ if $x \in S' \setminus \{u\}$. Of course, this simple approach is inefficient when $S'$ is not finite.
deciding whether $P_{E,S,u}$ is true seems to be in the folklore of algebraic number theory,\(^2\) and as far as the author knows, there was no example before this paper of such a triple $(E, S, u)$ where the answer was known. Note that although local Galois groups are pro-solvable, it does not seem possible\(^3\) to deduce property $P_{E,S,u}$ by induction from class field theory (or by the Grunwald–Wang theorem [AT68, p. 105]), the obstructions given by units forcing us to enlarge $S$ at each step (see also Proposition 4.1). Let us mention also that a weak version of $P_{E,S,u}$ is known by the work of Kuz’min and Mukhamedov [Muk84] (see also [NSW00, ch. X, §6, Theorem 10.6.4 and the last exercise]) concerning $p$-extensions of CM fields. For example, the following result is proved in [Muk84]. Let $p$ be a prime number and let $E$ be a CM field with maximal totally real subfield $F$ such that each prime $v$ of $F$ dividing $p$ splits in $E$. If $v$ is such a place, then the canonical maps

$$\text{Gal}(\mathcal{F}_v/F_v)_p \longrightarrow \text{Gal}((E_{(p,\infty)})/E)_p,$$

are injective. In this statement, $H_p$ denotes the maximal pro-$p$-quotient of the profinite group $H$. However, there seems to be no way to deduce property $P_{E,\{\infty,p\},v}$ from these. We come now to our main results.

**Theorem 1.1.** Assume that $E$ is a CM field and that $u$ is split above a finite place $v$ of the maximal totally real subfield $F$ of $E$. If $l$ is a rational prime number which is prime to $v$, and if $S$ is the set of places of $E$ dividing $lv$, then $P_{E,S,u}$ holds.

**Corollary 1.1.** If $E$ and $S$ are as in Theorem 1.1, then any integer $n \geq 1$ divides the pro-cardinal of $\text{Gal}(E_S/E)$.

Indeed, this last property is a general consequence of $P_{E,S,u}$ when $u$ is finite, as $\text{Gal}(\mathcal{F}_u/E_u)$ then has a continuous surjective homomorphism to $\hat{\mathbb{Z}}$. As Milne pointed out to us, this corollary answers in some cases a question raised in [Mil86, ch. I, §4] (concerning the set $P$ defined there). Note that the hypotheses of Theorem 1.1 are satisfied, for instance, if $E$ is a quadratic imaginary field split at a prime number $v = p$, and $l$ is a prime not equal to $p$. It has the following consequence for $E = \mathbb{Q}$.

**Corollary 1.2.** Let $p$ be a prime number, $N$ an integer such that $-N$ is the discriminant of an imaginary quadratic field in which $p$ splits, and let $S$ be the set of primes dividing $Np\infty$. Then $P_{\mathbb{Q},p,S}$ holds.

Explicit examples are given by $(p, N) \in \{(2, 7), (3, 2^2), (3, 11), (5, 2^2), (5, 11), (7, 3), \ldots \}$. In fact, as we will see later, we certainly conjecture that if $p$ and $l$ are distinct primes, then $P_{\mathbb{Q},\{\infty,p,l\},p}$ holds.

**Theorem 1.2.** Let $p$ and $l$ be any distinct prime numbers, and assume that Hypotheses 1 and 2 hold (see §5.1), then $P_{\mathbb{Q},\{\infty,p,l\},p}$ holds.

Although it is tempting to conjecture that $P_{\mathbb{Q},\{\infty,l\},l}$ holds, we are unfortunately less definite in this case (see §5.2).

Let us describe a bit the strategy of the proofs. First, we have to construct a lot of number fields unramified outside a given set of places $S$. By a well-known result of Grothendieck, the number fields attached to the $l$-adic étale cohomology of a proper smooth scheme $X$ over $E$ satisfy this property if $X$ has good reduction outside $S$, and if $S$ contains the primes dividing $l$. Although it

\(^2\)In particular, it had been asked by Ralph Greenberg after a related question raised by James Milne concerning the procardinal of $\text{Gal}(E_S/E)$ (see [Mil86, ch. I, §4] and our Corollary 1.1).

\(^3\)The author confesses that he did not manage to prove that ‘the maximal pro-solvable extension of $E$ inside $E_S$ is not dense in $E_u$’, although it seems reasonable.
might be very difficult in general to find such an $X$ ($S$ being given), well chosen Shimura varieties give some interesting examples. Even better, their $l$-adic cohomology is completely described, at least conjecturally, by the Langlands conjectures, in terms of cohomological automorphic forms. By the work of many authors, culminating in Harris and Taylor’s proof of local Langlands conjecture for $GL_n$, a big part of these conjectures is known for the so-called ‘simple’ Shimura varieties, which are attached to some unitary groups. This combined with some other tricks allowed Harris and Taylor to attach an $l$-adic representation to a wide class of cuspidal automorphic forms for $GL_n(\mathbb{A}_E)$ (see [HT01, Theorem C]), compatible with the local Langlands correspondence at all finite places not dividing $l$. Thus, we first show that we can construct cuspidal automorphic forms for $GL_n(\mathbb{A}_E)$ satisfying Harris–Taylor’s conditions, and which are unramified outside $S$ and of given ‘ramification type’ at $u$. More precisely, we first construct some automorphic forms on well-chosen unitary groups and apply quadratic base-change to them (§§ 2.1 and 2.2). By Harris and Taylor’s result, their associated $l$-adic Galois representations give us number fields with the required local properties and some control at $u$ (§ 3.1). The local Langlands correspondence shows then that we can produce in this way many such number fields, using unitary groups of all ranks. Two little subtleties arise at this point. First, we have little control, of course, on the Weil numbers in the above constructions, i.e. on the unramified part of the completion at $u$ of the number fields constructed. The second is that the automorphic representations we consider must fulfill some conditions so that we may apply to them the results of Harris and Taylor and the known cases of quadratic base change. However, a simple trick (§ 3.2) allows us to show that we produced sufficiently many number fields to prove Theorem 1.1.

As the sketch above shows, a question closely related to our initial aim is to ask if there exists pure motives over $E$ with ‘reduction type’ prescribed at each finite place (and, say, generic Hodge numbers). On the automorphic side, it leads to the purely analytic problem of constructing non-trivial, discrete, algebraic automorphic forms for a given reductive $\mathbb{Q}$-group $H$, with prescribed properties at all finite places. Of course, it is not always possible, e.g. an anisotropic torus has this property if and only if its real points are compact. In § 4, we show how to construct these automorphic forms under the following hypothesis on $H$: its center has finite arithmetic subgroups and $H(\mathbb{R})$ has a holomorphic discrete series. This result was probably known to specialists, but we could not find any convenient reference in this generality. By similar arguments as in the proof of Theorem 1.1, and using these automorphic representations, we explain in the last section some consequences concerning property $P_{E,S,u}$ of some standard conjectures in the arithmetic theory of automorphic forms. In particular, we obtain Theorem 1.2.

Notation

If $F$ and $G$ are two subfields of a given field, we denote by $F,G$ the subfield generated by $F$ and $G$. This is also the $F$-vector space generated by $G$ if $G$ is algebraic over $F \cap G$. If $K$ is a field, $\overline{K}$ denotes a separable algebraic closure of $K$, and $G_K := \text{Gal}(\overline{K}/K)$ its absolute Galois group, equipped with its Krull topology. If $\rho: G_K \to H$ is any continuous group homomorphism to a topological group $H$, we denote by $K(\rho) := \overline{K}^{\text{Ker}(\rho)}$ the algebraic normal extension of $K$ fixed by $\text{Ker}(\rho)$. We say that $K(\rho)$ is the extension of $K$ cut out by $\rho$. If $K$ is a finite extension of $\mathbb{Q}_p$, $K^{ur} \subset \overline{K}$ denotes its maximal unramified extension, $W_K \subset G_K$ its Weil group, and $I_K = \text{Gal}(\overline{K}/K^{ur}) \subset W_K$ its inertia group. If $F$ is a number field, $\mathbb{A}_F$ denotes the adèle ring of $F$ and $\mathbb{A}_{F,f}$ its quotient of finite ones. If $p+q = n$, we denote by $\mathcal{U}(p,q)$ the real unitary group of signature $(p,q)$, and we set $\mathcal{U}(n) := \mathcal{U}(n,0)$.

2. Construction of some automorphic forms I

Let $E$ be a CM field as in the statement of Theorem 1.1. Let us fix a finite place $u$ of $F$ dividing the prime number $l$ (in particular, $w \neq v$), and let $n \geq 1$ be an integer.
2.1 Some unitary groups

We want to consider unitary groups attached to central division algebras over \( E \), which are quasisplit at each finite place not equal to \( w, v \), and compact at infinite places for convenience. The relevant ‘Hasse principle’ is known and due to Kneser. We refer to Clozel’s paper [Clo91, §2] for a convenient exposition of Kottwitz’ interpretation of Kneser’s results in the special case of unitary groups.

**Lemma 2.1.** There exists a unitary group \( U(n) \) over \( E/F \) such that for a place \( x \) of \( F \), \( U(n)(F_x) \) is:

(a) quasisplit if \( x \) is a finite place not dividing \( uv \);
(b) the group of units of a central division algebra over \( F_x \) if \( x = v \);
(c) the compact real unitary group if \( x \) is real.

**Proof.** If \( n \) is odd, there is no global obstruction to the existence of such groups by [Clo91, Lemma 2.1]. Assume \( n \) is even. By [Clo91, (2.2)], the global obstruction lies in \( \mathbb{Z}/2\mathbb{Z} \) and is the sum of all local ones modulo 2. Assuming given local groups satisfying parts (a), (b), and (c), we can make the global invariant vanish by requiring, if necessary, that \( U(n)(F_w) \) is either a non-quasisplit unitary group or the units of a division algebra, because such groups have local invariant equivalent to 1 mod 2 by [Clo91, (2.3)]. This concludes the proof. \( \square \)

2.2 Construction of automorphic forms

Let \( H/F \) be the unitary group \( U(n) \) given by Lemma 2.1. The group \( H(F_v) \) is the group of units of a central division algebra \( D \) over \( F_v \) of rank \( n^2 \). Let \( \pi \) be an irreducible, finite-dimensional, complex smooth representation of \( D^* \).

**Lemma 2.2.** There exists an irreducible automorphic representation \( \Pi \) of \( H(\mathbb{A}_F) \) such that:

(a) if \( x \neq v \), \( w \) is finite place, then \( \Pi_x \) is unramified;
(b) \( \Pi_v \simeq \pi \otimes \psi \) for some unramified character \( \psi : D^* \to \mathbb{C}^* \).

**Proof.** We first choose, for each finite place \( x \) of \( F \), a particular compact open subgroup \( J_x \) of \( H(F_x) \). If \( x \) is different from \( v \) and \( w \), \( H(F_x) \) is quasisplit so that we can take for \( J_x \) a maximal compact subgroup which is very special in the sense of [Lab98, §3.6] (when \( x \) does not ramify in \( E \), the hyperspecial compact subgroups of \( H(F_x) \) are very special; for almost all \( x \) we may and want to take \( J_x = H(\mathcal{O}_{F_x}) \)).

For such a place \( x \), an irreducible admissible representation of \( H(F_x) \) will be said to be unramified if it has a nonzero vector invariant by \( J_x \). If \( x = v \), we take \( J_x = \mathcal{O}_D^* \) and we fix an irreducible constituent \( \tau_v \) of \( \pi|_{J_v} \). If \( x = w \), we take any compact open subgroup of \( H(F_x) \) for \( J_x \).

Let \( J := \prod_x J_x \), it is a compact open subgroup of \( H(\mathbb{A}_{F,J}) \). Let \( \tau \) be the trivial extension to \( J \) of the representation \( \tau_v \) of \( J_v \), via the canonical projection \( J \to J_v \).

As \( H_\infty := H(F \otimes_{\mathbb{Q}} \mathbb{R}) \) is compact, the group \( H(F) \) is discrete in \( H(\mathbb{A}_{F,J}) \). In particular, \( \Gamma := H(F) \cap J \) is a finite-group. For any continuous (finite-dimensional), complex representation \( W \) of \( H_\infty \), we set \( W(\tau) := \otimes \tau^* \) viewed as an \( H_\infty \times J \)-representation. By the Peter–Weyl theorem, we can find an irreducible \( W \) such that \( W|_{\Gamma} \) contains a copy of \( \tau \), and so a nonzero element \( v \in W(\tau)^\Gamma \) (for the diagonal action of \( \Gamma \)). We choose moreover an element \( \varphi \in W(\tau)^* \) such that \( \varphi(v) = 1 \). Let \( h : H_\infty \times J \to \mathbb{C} \) be the coefficient of \( W(\tau) \) defined by \( h(z) := \varphi(z^{-1}v) \).

By construction, \( h \) is smooth, left \( \Gamma \)-invariant, and generates copies of \( W(\tau)^* \) under the right translations by \( H_\infty \times J \), because \( W(\tau) \) is irreducible. It is nonzero because \( h(1) = 1 \). It extends then uniquely to a smooth map \( f_h : H(\mathbb{A}_F) \to \mathbb{C} \) null outside the open subset \( H(F).(H_\infty \times J) \) and satisfying \( f_h(\gamma z) = f_h(z) \), for all \( \gamma \in H(F), z \in H(\mathbb{A}_F) \), i.e. which is an automorphic form for \( H \). Let \( \Pi \subset L^2(H(F)\backslash H(\mathbb{A}_F), \mathbb{C}) \) be an irreducible constituent of the \( H(\mathbb{A}_F) \)-representation generated by \( f_h \).
3. Proof of Theorem I

3.1 Construction of S-unramified number fields

With the assumptions of §2, let S be the set of places of E dividing lv. We fix an embedding \( \varphi : E_S \to \overline{E}_v \) extending the F-embedding \( E \to \overline{E}_v \) given by u. Let us use the notation

\[ G_{E,S} := \text{Gal}(E_S/E). \]

Attached to \( \varphi \) is a group homomorphism \( G_{E_v} \to G_{E,S} \) (see the introduction for the notation). We keep the assumption of §2.2, and we choose a \( \Pi \) given by Lemma 2.2. We assume from now on that \( \pi \) corresponds to a supercuspidal representation of \( GL_n(F_v) \) by the Jacquet–Langlands correspondence, that is \( \dim_\mathbb{C}(\pi) > 1 \) if \( n > 1 \). The local Langlands correspondence (see [HT01]) associates to \( \pi \) an continuous, irreducible, representation

\[ \psi_\pi : W_{E_v} \longrightarrow GL_n(\mathbb{C}). \]

Let \( F_v^{ur}(\pi) \subset \overline{E}_v \) be the finite extension of \( F_v^{ur} \) which is fixed by \( \text{Ker}( (\psi_\pi)|_{T_{E_v}}) \), that is the extension of \( F_v^{ur} \) cut out by \( (\psi_\pi)|_{T_{E_v}} \). Recall that \( l \) is prime to \( v \) and fix embeddings \( t_l : \overline{\mathbb{Q}} \to \overline{\mathbb{Q}}_l \) and \( t_\infty : \overline{\mathbb{Q}} \to \mathbb{C} \).

**Lemma 3.1.** We have the following:

(i) there exists a continuous representation

\[ R : G_{E,S} \to GL_n(\overline{\mathbb{Q}}_l), \]

such that \( R|_{W_{E_v}} \) corresponds to \( \Pi_v \otimes |\det|^{(n-1)/2} \) by the local Langlands correspondence;

(ii) \( F_v^{ur} \cdot \varphi(E_S) \supset F_v^{ur}(\pi) \).

**Proof.** This lemma is a consequence of conditional automorphic base change [Clo91, CL98, HL04], of Jacquet–Langlands correspondence, and of the main theorem of Harris and Taylor [HT01].

Precisely, let us denote by BC the quadratic base change from \( H \) to \( H' := \text{Res}_{E/F}(H \times_F E) \).

By Theorem 3.1.3 of [HL04] (generalizing [CL98, Theorem A.5.2] and [Clo91]), there is a cuspidal automorphic representation \( \Pi' \) of \( H' \) such that \( \Pi'_x = BC(\Pi_x) \) for each place \( x \neq w \) of \( F \). It applies because \( \Pi_\infty \) is automatically cohomological as \( H(F \otimes_{\mathbb{Q}} \mathbb{R}) \) is compact, and because \( H \) is attached to a division algebra, as \( H(F_v) \) is. Note that BC has been defined for unramified representations at the places \( x \) such that \( H(F_v) \) is a ramified, quasisplit, unitary group, in [Lab98, §3.6, Proposition 3.6.4]. In particular, \( \Pi'_x \) is unramified if \( x \notin S \), \( \Pi'_v = \Pi_v \otimes \Pi^*, \) and \( \Pi'_\infty \) has the

\[ \text{As Labesse explained to us, the confusing hypothesis ‘}G\text{’ is unramified, and }K^G\text{ is hyperspecial’ in [Lab98, Proposition 3.6.4] should be understood as ‘}G_0\text{ is unramified over }E_x,\text{ and }K^G_0\text{ is hyperspecial viewed as a subgroup of }G_0(E_x)\text{’ (for us }G_0 = GL_n(E_x))\text{, so as to be of any use, and the same proof applies verbatim. If we did not use these facts, we would be obliged to add, in the set }S\text{ of the theorem, the places of }E\text{ ramified above }F\text{. Note, however, that this would suffice to obtain Corollary 1.2.} \]
base change infinitesimal character. We can then apply\textsuperscript{5} [HT01, Theorem C] to the image $JL(\Pi')$ of $\Pi'$ by the Jacquet–Langlands correspondence (due to Vignéras, see [HT01, Theorem VI.1.1]), and consider

$$R := R_I(JL(\Pi'))$$

given by [HT01] and the embeddings $i_t, i_\infty$, which proves assertion (i).

We check the second assertion. Let us denote by $E_S(R)$ the subfield of $E_S$ fixed by $\text{Ker}(R)$. As $\text{Gal}(\overline{F}/(F, \varphi(E_S(R)))) = \text{Ker}(R_{|G_{F_v}})$, Galois theory shows that

$$F_v, \varphi(E_S(R)) = F_v(R_{|G_{F_v}}).$$

By assertion (i), $\psi_{\text{IL}}$ is defined over $t_\infty(\mathbb{Q})$ and $R_{|F_v} \simeq i_t, i_\infty^{-1}(\psi_{\text{IL}})|_{F_v}$ (it has finite image), so that $F_v^\text{ur}(R_{|F_v}) = F_v^\text{ur}(\psi_{\text{IL}})$. However, by Lemma 2.2, $\pi$ and $\Pi_v \otimes |\det|^{(n-1)/2}$ only differ by an unramified twist, hence $\psi_{\text{IL}} \otimes |\det|^{(n-1)/2}$ and $\psi_\pi$ are equal when restricted to $I_{F_v}$. In particular, $F_v^\text{ur}(\pi) := F_v^\text{ur}(\psi_\pi) = F_v^\text{ur}(\psi_{\text{IL}})$, and we conclude as $F_v^\text{ur}.F_v(R_{|G_{F_v}}) = F_v^\text{ur}(R_{|F_v})$.

\textbf{3.2 End of the proof}

\textbf{Lemma 3.2.} Let $\mathbb{Q}_p \subset M \subset L \subset \overline{M}$ be a tower of field extensions with $M/\mathbb{Q}_p$ finite.

(i) Assume that $\text{L}/M$ is Galois and $M^\text{ur}.L = \overline{M}$, then $L = \overline{M}$.

(ii) If $\sigma \in G_M$ acts trivially by conjugation on the tame inertia of $I_M$, then $\sigma \in I_M$.

(iii) Assume that for all finite Galois extension $K/M$ such that $\text{Gal}(K/M)$ admits an injective, irreducible, complex linear representation, we have $K \subset L$; then $L = \overline{M}$.

\textbf{Proof. } (i) Let $H := \text{Gal}(\overline{M}/L) \subset G_M$. By assumption, $H$ is normal in $\Gamma$ and $H \cap I_M = \{1\}$, hence $I_M/H \simeq I_M \times H$ is a direct product and part (i) (i.e. $H = \{1\}$) is an immediate consequence of part (ii), which we now prove.

Let $I_M^r$ be the tame inertia quotient of $I_M$, recall that there is an isomorphism

$$I_M^r \simeq \prod_{l \neq p} \mathbb{Z}_l(1),$$

which means that the action of $\Gamma$ by conjugation on $I_M^r$, which factors through the canonical map $\nu : \text{Gal}(M^\text{ur}/M) \to \hat{\mathbb{Z}}$, is the multiplication by $q^\nu(\gamma) \in \prod_{l \neq p} \mathbb{Z}_l(1)$, where $q$ is the cardinal of the residue field of $K$. Let $\gamma \in \Gamma$ such that $q^\nu(\gamma) = 1$, we aim to prove that $\nu(\gamma) = 0$. We claim that for any integers $m \geq 2$ and $r \geq 1$, we can find infinitely many primes $l$ such that $r$ divides the order of $m$ in $\mathbb{F}_l^\times$. Applying this claim to $m = q$, we get that $r$ divides $\nu(\gamma)$ for all $r \geq 1$, i.e. $\nu(\gamma) = 0$. Let us prove the claim now (see also Van der Waerden’s lemma [Lan94, ch. X, § 2, Lemma 1]). Note that if $P \in \mathbb{Z}[X]$ is such that $P(0) \neq 0$ and $m \geq 2$ is an integer, then the sequence $(P(m^N))_{N \geq 1}$ admits infinitely many prime divisors. Indeed, assuming that the assertion is false, we can find a prime $p$ such that each power of $p$ divides $P(m^N)$ for some $N$. As $P(0) \neq 0$, $p$ is prime to $m$. Thus, if we let $N$ go to infinity, we get that $P(1) = 0$ in $\mathbb{Z}_p$. This is a contradiction, as $P = X - 1$ certainly satisfies the assertion. The claim then follows from the special case $P := r$th cyclotomic polynomial.

We now show part (iii). Let $K/M$ be any finite Galois extension, $\rho_1, \ldots, \rho_t$ the irreducible, complex, linear representations of $\text{Gal}(K/M)$, and $K_i \subset L$ the fixed field of $\text{Ker}(\rho_i)$. By assumption, $K_i \subset L$. The existence of the (faithful) regular representation of $\text{Gal}(K/M)$ implies that $\bigcap_i \text{Ker}(\rho_i) = \{1\}$, so that by Galois theory we have $K = K_1 \ldots K_t$, and $K \subset L$.

\textbf{5Note} that $JL(\Pi')$ is cuspidal by Moeglin–Waldspurger’s description of the discrete spectrum of $GL_n$, because $JL(\Pi')_c = JL(\Pi'_c)$ is supercuspidal.

1364
ON NUMBER FIELDS WITH GIVEN RAMIFICATION

Let us finish the proof of Theorem 1.1. Let $K/F_v$ be a finite Galois extension such that $\text{Gal}(K/F_v)$ admits an irreducible injective representation $\rho : \text{Gal}(K/F_v) \to \text{GL}_n(\mathbb{C})$. The local Langlands correspondence and the Jacquet–Langlands correspondence associate to $\rho$ an irreducible smooth representation $\pi$ of $D^*/F_v$ such that $\psi_v$ factors through $\rho$. Lemma 3.1(ii) shows that $F^\text{ur}_v.\varphi(E_S) \supset F^\text{ur}_v.\pi$. However, $F^\text{ur}_v.\pi = F^\text{ur}_v.K$, as $\rho$ is injective. We have thus shown that $K \subset F^\text{ur}_v.\varphi(E_S)$. Applying Lemma 3.2(iii) to $M = F_v$ and $L = F^\text{ur}_v.\varphi(E_S)$, we conclude that $F^\text{ur}_v.\varphi(E_S) = F_v$. Applying now Lemma 3.2(i) to $M = F_v$ and $L = F_v.\varphi(E_S)$, we get Theorem 1.1. \hfill $\square$

4. Construction of some automorphic forms II

In this section, we generalize some results of § 2 concerning the construction of automorphic representations with prescribed properties. Let $H$ be a connected reductive group over $\mathbb{Q}$, let $J$ be a compact open subgroup of $H(\mathbb{A}_{\mathbb{Q},f})$, and let $\tau$ be a fixed, irreducible, smooth representation of $H$. We aim to construct discrete, algebraic, automorphic representations $\Pi$ of $H$, such that $\Pi_{f,\mathbb{Q}}$ contains $\tau$. From the point of view of types theory (see [BK98]), it allows us to prescribe the inertial equivalence class of each $\Pi_v$ with $v$ finite. For example, in the case of $\text{GL}_n$ over a local field, the inertial equivalent class of a smooth irreducible representation determines the restriction to the inertia group of its Langlands parameter, hence types control the ramification in a strong sense. In general, it seems hard to prescribe more properties of $\Pi_v$, as we certainly cannot guess easily its Weil numbers if $v$ is unramified for instance. Note moreover that such a $\Pi$ may not exist, as the obstruction given by units shows in the example of the torus $H = \text{Res}_{E/\mathbb{Q}}(\mathbb{G}_m/E)$ when $E \neq \mathbb{Q}$ is not quadratic imaginary.

4.1 Let $H$ be as above and let $Z$ denote its center. We assume that:

- (A) $H(\mathbb{R})$ has a holomorphic discrete series (i.e. the derived Lie algebra of $H(\mathbb{R})$ satisfies (1) of § 4.2);
- (B) $Z(\mathbb{Q})$ is discrete in $Z(\mathbb{A}_{\mathbb{Q},f})$.

**Proposition 4.1.** Let $H$ be as above, let $J$ be a compact open subgroup of $H(\mathbb{A}_{\mathbb{Q},f})$, and let $\tau$ be an irreducible smooth representation of $J$. There exists an irreducible, discrete, automorphic representation $\Pi$ of $H(\mathbb{A}_{\mathbb{Q}})$ such that $\Pi_{f,\mathbb{Q}}$ is in the holomorphic discrete series, and $\Pi_{f,\mathbb{Q}}$ contains $\tau$.

**Remarks.** Note that by [Bor69, Theorem 8.9], property (B) depends only of the isogeny class of $Z$. If $Z$ is anisotropic, it holds if and only if $Z(\mathbb{R})$ is compact by [Bor69, Theorem 8.7]. It happens for example when $E/F$ is CM and $Z = (\text{Res}_{E/\mathbb{Q}}(\mathbb{G}_m/E))^{\text{Gal}(E/F)}$. It is easy to see that properties (A) and (B) hold when $H$ is $\text{GL}_2/\mathbb{Q}$, $\text{GSp}_{2n}/\mathbb{Q}$, the scalar restriction to $\mathbb{Q}$ of a unitary group attached to a CM field, $\text{SO}(n,2)/\mathbb{Q}$, or when $H(\mathbb{R})$ is compact.

Before proving Proposition 4.1, we mention the following corollary. Let $E$ be a CM field, $F$ its maximal totally real subfield, $v$ a finite place of $F$ which splits in $E$, and write $v = uu'$.

**Corollary 4.1.** Let $\pi$ be a supercuspidal, irreducible, representation of $\text{GL}_n(E_u)$. There exists an automorphic cuspidal representation $\Pi$ of $\text{GL}_n(\mathbb{A}_E)$ satisfying $\Pi^c \simeq \Pi^*$, and such that:

- (a) $\Pi$ is unramified outside $u, u'$, and $\Pi_u$ is an unramified twist of $\pi$,
- (b) for any $x$ archimedean, $\Pi_x$ has a regular algebraic infinitesimal character.

**Proof.** By the same reasoning as in the proof of Lemma 2.1, Hasse’s principle shows that there exists a unitary group $U(n)/F$ attached to $E/F$ which is quasi-is split at all finite places not equal to $v$, and the group of invertible elements of a central division algebra over $F_v \simeq E_u$ at $v$. In fact,
as the local invariant of $U(m + r, m - r)$ is $r$ mod 2 by [Clo91, lemme 2.2], we could even assume that $U(n)$ is compact at all archimedean places, except maybe one where it is $U(n - 1, 1)$. Then $H := \text{Res}_{E/Q} U(n)$ satisfies the hypothesis of Proposition 4.1, by the remarks above. Let $\pi' := JL^{-1}(\pi)$ be the finite-dimensional representation of $U(n)(F_v)$ corresponding to $\pi$ by the Jacquet–Langlands correspondence. By choosing a suitable compact open subgroup $J$ of $H(k_{Q,f})$ as in the proof of Lemma 2.2, Proposition 4.1 produces an automorphic discrete representation $\Pi'$ of $U(n)/F$ which is unramified outside $v$, such that $\Pi'_v$ is a twist of $\pi'$ by an unramified character, and whose archimedean components are discrete series (hence, cohomological by [BW80, Theorem 5.3(b)]). As we are in the hypothesis of the ‘conditional’ quadratic base change, we conclude as in the proof of Lemma 3.1(i) that $\Pi := JL(BC(\Pi'))$ satisfies all of the hypotheses of the corollary. 

Note that Proposition 4.1 is a generalization of Lemma 2.2, and the same proof as that of Lemma 2.2 would allow us to conclude verbatim when $H(\mathbb{R})$ is compact.\(^6\) The general case relies on more delicate analytic facts. We are very grateful to Laurent Clozel for explaining to us an argument using the Selberg trace formula, holding even under the assumption that $H(\mathbb{R})$ has a discrete series. In what follows, we give an argument using Poincaré series going back to Poincaré, Cartan and Godement (see [Bor97, ch. 6], [Car53, exposé 1], and [Car57, exposés 6 and 10]; see also [Car57, exposé 10] for the detailed case $H_{\infty} = \text{GSp}_{2g}(\mathbb{R})$ and most of the ideas of the general argument), so that Proposition 4.1 should certainly not be considered as original. Roughly, the difficulty is twofold. First, we want to use coefficients of square integrable representations of $H(\mathbb{R})$ to ensure the convergence of some Poincaré series. Then, we must have a sufficiently good control on these coefficients to produce some non-identically zero automorphic forms. Thus, as a preliminary, we recall in §4.2 some facts about Harish-Chandra’s realization of the holomorphic discrete series (due to Harish-Chandra).

### 4.2 Holomorphic discrete series

In this section, we follow closely Knapp’s book [Kna86, ch. VI]. Let $G$ be a real, connected, reductive Lie group, and $K$ a maximal compact subgroup. Assume that a Cartan decomposition $g = \mathfrak{k} \oplus \mathfrak{p}$ satisfies

$$Z_{\mathfrak{g}}(c) = \mathfrak{k}, \quad (1)$$

where $c$ is the center of $\mathfrak{k}$. For example, it is easily seen to be the case for any $U(p, q)$ and for symplectic groups (see [Kna86, ch. VI, §2]). Let $\mathfrak{h} \subset \mathfrak{k}$ be a Cartan subalgebra, associated to a Cartan subgroup $T \subset K$, and let $\mathfrak{g}^C = \mathfrak{h}^C \bigoplus_{\alpha \in \Delta} \mathfrak{g}_\alpha$ be its associated root space decomposition.

Recall that a root $\alpha \in \Delta$ is said to be noncompact (respectively compact), if $\mathfrak{g}_\alpha \subset \mathfrak{p}^C$ (respectively in $\mathfrak{t}^C$). This notion gives us a partition $\Delta = \Delta_n \bigsqcup \Delta_k$. We fix a good ordering on $\mathfrak{h}_R^*$, i.e. with the property that any positive noncompact root is bigger than any compact root. We set $\mathfrak{p}^\pm := \bigoplus_{\alpha \in \Delta_k^\pm} \mathfrak{g}_\alpha$, these are abelian Lie subalgebras of $\mathfrak{p}^C$ which are stable by $\text{ad}(\mathfrak{k})$. We fix a complex matrix group $G_C$ whose Lie algebra is $\mathfrak{g}^C$, and we let $K_C$ and $P^\pm$ be the complex analytic subgroups of $G_C$ with Lie algebras $\mathfrak{t}^C$ and $\mathfrak{p}^\pm$, as in [Kna86, ch. VI, §3]. By Harish-Chandra’s decomposition, the natural product map $P^+ \times K_C \times P^- \to G_C$ is a complex open immersion, and $G K_C P^- \subset G_C$ is an open subset, and so inherits the complex structure of $G_C$. Moreover, there exists a bounded open domain $\Omega \subset P^+ \simeq \mathbb{C}^r$ such that $\Omega K_C P^- = G K_C P^-$. As $G \cap K_C P^- = K$, the $G$-orbit of $1 \in G_C/K_C P^-$ is $G/K \simeq \Omega$.

Let us fix an analytically integral $\lambda \in \mathfrak{h}_R^*$, which is dominant restricted to $\Delta_k^\pm$, and let $W_\lambda$ be the irreducible representation of $K_C$ of highest weight $\lambda$. This $W_\lambda$ gives rise to a complex algebraic vector

---

\(^6\)For the sake of exposition, and as much of the difficulty disappears in the compact case, we found it convenient to separate the proof. Moreover, Lemma 2.2 is not only sufficient for the proof of Theorem 1.1, but also fix some ideas about the general case.
bundle on the Grassmannian \( G_C/K_C P^- \), and we want to consider holomorphic, square integrable, sections of this bundle on \( \Omega \). Concretely, we fix a definite, \( K \)-invariant, hermitian product on \( W_\lambda \), and we consider the vector space \( V_\lambda \) of \( W_\lambda \)-valued functions \( f \) on \( G \) satisfying:

(i) for all \( g \in G \), and all \( k \in K \), \( f(gk) = k^{-1} f(g) \);

(ii) \( f \) is holomorphic (see below);

(iii) \( \int_G |f(g)|^2 \, dg < \infty \).

For a map \( f : G \to W_\lambda \) satisfying part (i), part (iii) means that the canonical \( P^- \)-invariant extension of \( f \) to \( GK_C P^- \) is holomorphic. Note that \( V_\lambda \) is in a natural way a module over the ring of bounded holomorphic functions on \( \Omega \), and a unitary representation \( L_\lambda \) of \( G \) by left translation.

Let \( \delta := \frac{1}{2} \sum_{\alpha \in \Delta^+} \alpha \). We can now state Harish-Chandra’s theorem \([\text{Kna}86, \text{Theorem 6.6}]\).

**Theorem** (Harish-Chandra). Assume that \( \langle \lambda + \rho, \alpha \rangle < 0 \) for all \( \alpha \in \Delta_+^\vee \). Then \( V_\lambda \) is a nonzero Hilbert space, and \( L_\lambda \) is an irreducible, square-integrable, \( G \)-representation.

We consider now a special case related to the standard jacobian automorphy factor on \( \Omega \). Let \( \rho_n := \sum_{\alpha \in \Delta_+^\vee} \alpha \in h^\vee \). We claim that \( \rho_n \) is analytically integral, dominant, and satisfies

\[
\langle \rho_n, \alpha \rangle > 0, \quad \forall \alpha \in \Delta_+^\vee.
\]

Indeed, if \( p := \dim_C p^+ \), then \( \rho_n \) is the weight of the one-dimensional representation \( \Lambda^p p^+ \) of \( \mathfrak{h} \). In particular, for all \( m \in \mathbb{Z} \), \( m \rho_n \) is analytically integral, and dominant with respect to \( \Delta_+^\vee \). Moreover, by the definition of the ordering, \( \rho_n \) is also the highest weight of the natural representation of \( g \) on \( \Lambda^p g^C \supset \Lambda^p p^+ \), and so is dominant. The last part of the claim follows, as the parabolic subalgebra \( \mathfrak{h}^C \oplus p^+ \) is its own normalizer in \( g^C \).

As a consequence, we can fix an integer \( r > 0 \) such that \( \delta := -r \rho_n \) satisfies the hypothesis of Harish-Chandra’s theorem. Let us fix an element \( j \in V_\delta \) which is an eigenvector for the left translations by \( K \), and satisfies \( \langle j|1 \rangle = 1 \). Such an element exists: we can take the one denoted by \( \psi_\lambda \) in \([\text{Kna}86, \text{Lemma 6.7}]\). By Harish-Chandra’s convolution theorem (see \([\text{Kna}86, \text{Corollary 8.41}]\) and \([\text{Bor}97, \text{Corollary 2.22}]\)), \( K \)-finite elements of \( V_\lambda \) are bounded on \( G \), and so is \( j \). In particular, if \( f \in V_\lambda \) and if \( m \geq 0 \) is an integer, then \( (f \cdot j^m)(g) := f(g) \otimes j^m(g) \) defines an element in \( V_{\lambda + m \delta} \). For convenience, we often identify the one-dimensional vector space \( W_\delta \) with \( C \), taking \( j(1) \) as a norm one basis element.

**Example.** Let \( G := U(n-1,1) \), let \( K \) be the diagonal \( U(n-1) \times U(1) \), and let \( T \subset K \) be the diagonal torus. We can choose a good ordering on the roots such that \( \sum_{\alpha \in \Delta^+} \alpha \) is the standard upper Borel subalgebra in \( g^C = g^\vee \). In this case, \( K_C P^- \) identifies with the standard lower parabolic of \( G_C = GL_n(C) \) of type \( (n-1,1) \). The bounded domain \( \Omega \) identifies with the open unit hermitian ball of \( C^{n-1} = P^- \subset G_C/K_C P^- = \mathbb{P}^{n-1}(C) \). We define \( e_i \in h^\vee_R \) by \( e_i(x_1, \ldots, x_n) := x_i \). With these choices, \( \Delta^+_n = \{ e_i - e_n, 1 \leq i < n \} \) and \( \Delta^+_K = \{ e_i - e_j, 1 \leq i < j < n \} \). Then \( \lambda = \sum_{i=1}^n m_i e_i \) satisfies the hypothesis of Harish-Chandra’s theorem if, and only if, \( m_1 \geq m_2 \geq \cdots \geq m_{n-1}, \)

\( m_n > m_1 + (n - 1) \), and for all \( i, m_i \in \mathbb{Z} \). We have \( \rho_n = (e_1 + \cdots + e_{n-1}) - (n-1)e_n \), and we can take \( \delta = -2 \rho_n \).

### 4.3 Convergence of Poincaré series

We now begin the proof of Proposition 4.1. Let \( Z_c \) denote the maximal compact subgroup of \( Z(\mathbb{R}) \) (viewed as a real Lie group) and write \( Z(\mathbb{R}) = Z_n \times Z_c \) for some closed subgroup \( Z_n \) isomorphic to

\[376\]

The identification of the space of functions on \( U \) with that from \([\text{Kna}86, \text{Theorem 6.6}]\) comes from Borel–Weil–Bott realization of \( W_\lambda \) \([\text{Kna}86, \text{Theorem 5.29}]\).
some $\mathbb{R}^m$. Let $G$ denote the closed connected subgroup of the Lie group $H(\mathbb{R})$ whose Lie algebra is $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{j}_c$. If $H(\mathbb{R})^+$ denotes the neutral component of the real Lie group $H(\mathbb{R})$, then

$$H(\mathbb{R})^+ = Z_n \times G.$$ 

Let $\Gamma \subset H(\mathbb{R})^+$ be the discrete subgroup $H(\mathbb{Q}) \cap (H(\mathbb{R})^+ \times J)$, let us show that $\Gamma \subset G$. Let $C$ be the $\mathbb{Q}$-torus $H/H_{deq}$ and det : $H \to C$ be the canonical $\mathbb{Q}$-morphism. Note that det induces a $\mathbb{Q}$-isogeny $Z \to C$, hence $C$ has finite arithmetic groups by assumption (B) and [Bor69, Theorem 8.9]. In particular, det$(\Gamma) \subset C(\mathbb{Q})$ is a finite subgroup. However, the induced map det : $H(\mathbb{R})^+ \to C(\mathbb{R})$ is injective restricted to $Z_n$, and det$(G)$ is compact, hence $\Gamma \subset G$.

The Lie algebra $\mathfrak{g}$ satisfies (1) by assumption (A), so that we can apply to $G$ the constructions (and notation) of § 4.2. Let $\lambda \in \mathfrak{h}^*_\mathbb{R}$ be as in Harish-Chandra’s theorem, we set $V_\lambda(\tau) := V_\lambda \otimes \tau^*$, viewed as a representation of $G \times J$. We consider coefficients of $V_\lambda(\tau)$ of the following kind. Let $W_\lambda(\tau) := W_\lambda \otimes \tau^*$ viewed as before as a representation of $K \times J$. If $\varphi \in W_\lambda(\tau)^*$, we can see it as a continuous linear form $\tilde{\varphi}$ on $V_\lambda(\tau)$ by $f \mapsto \varphi(f(1))$. We define $h := h_{f,\varphi} : G \times J \to \mathbb{C}$ by $h(z) := \tilde{\varphi}(z^{-1}.f) = \varphi((1 \times z)^{-1}.f(z_G))$. The Poincaré series $P_h : G \times J \to \mathbb{C}$ is defined by

$$P_h(z) := \sum_{\gamma \in \Gamma} h(\gamma z).$$

We equip $W(\tau)$ with any hermitian norm $| \cdot |$ such that $K \times J$ acts by unitary transformations. As $f \in L^2(G)$, it comes that $P_h \in L^2_{\text{loc}}(G \times J)$. Indeed, if $U \subset G \times J$ is a compact set, then $\Gamma \cap (UU^{-1})$ is finite, hence

$$\sum_{\gamma \in \Gamma} \int_U |h(\gamma g)|^2 \, dg \leq |\Gamma \cap UU^{-1}| \int_{G \times J} |h(g)|^2 \, dg \leq C \int_G |f(g)|^2 \, dg < \infty,$$

where $C := \text{vol}(J) \cdot |\Gamma \cap UU^{-1}| \cdot \|\varphi\| > 0$. As all of the $g \mapsto f(\gamma.g)$ are in $V_\lambda$, and in particular holomorphic, $P_h$ converges in fact uniformly on any compact subset of $G \times J$, to a holomorphic function on $G \times J$ of right $K \times J$-type $W(\tau)^*$. In particular, we proved the following.

**Lemma 4.1.** Let $\lambda \in \mathfrak{h}^*_\mathbb{R}$ be as in Harish-Chandra’s theorem, and let $h$ be a coefficient of $V_\lambda(\tau)$ as above. The Poincaré series $P_h$ is normally convergent on any compact subset of $G \times J$.

### 4.4 Construction of nonvanishing Poincaré series

It remains to find a $\lambda$ and an $h$ such that $P_h \neq 0$. Let $\Gamma_0$ be the finite group $\Gamma \cap K$. As in the proof of Lemma 2.2, we can find a finite-dimensional, irreducible, complex representation $W = W_\lambda$ of $K$ such that $W_\lambda(\tau)^{\Gamma_0} \neq 0$. By twisting $W_\lambda$ by $W_m^{\mathbb{R}}$ for an integer $m \geq 0$ big enough and divisible by $|\Gamma_0|$, (2) shows that we may assume that $\lambda \in \mathfrak{h}^*_\mathbb{R}$ satisfies the hypothesis of Harish-Chandra’s theorem. We fix as before an element $v \in W_\lambda(\tau)^{\Gamma_0}$ of norm one and we choose a $\varphi \in W(\tau)^*$ of norm one such that $\varphi(v) = 1$. By Lemma 4.1 applied to $\lambda = \delta$ and to the coefficients associated to the function $j$ itself, we get that

$$\Gamma_1 := \{ \gamma \in \Gamma, |j(\gamma)| \geq 1 \}$$

is a finite subset of $\Gamma$, and $\Gamma_0 \subset \Gamma_1$. We claim that we can choose an $f \in V_\lambda(\tau)$ such that

$$f(1) = v \quad \text{and} \quad \forall \gamma \in \Gamma_1 \setminus \Gamma_0, \quad f(\gamma) = 0.$$ 

As $V_\lambda(\tau)$ is nonzero and stable by the action of $G \times J$, we can find a $f_1 \in V_\lambda(\tau)$, such that $f_1(1) \neq 0$. However, by irreducibility of $W_\lambda(\tau)$ as $K \times J$-representation, we can find in $\mathbb{C}[K \times J].f_1$ an element sending 1 to $v$. We can thus assume that $f_1(1) = v$. Then, we can multiply $f_1$ by a bounded holomorphic function $f_2$ on $\Omega$ such that $f_2(1) = 1$ and $f_2(\gamma) = 0$ if $\gamma \in \Gamma_1 \setminus \Gamma_0$, which certainly exists (e.g. restrictions to the bounded symmetric domain of polynomials on $P^+ = \mathbb{C}^p$). The function $f = f_1 f_2$ does the trick. This proves the claim.
On number fields with given ramification

For any \( m \geq 1 \) divisible by \( |\Gamma_0| \), let us consider the element \( v_m := v \otimes 1^m \in W_{\lambda+md}(\tau)^G \) and \( \varphi_m := \varphi \otimes \text{id}^m \in W_{\lambda+ms}(\tau)^* \). We still have \( \varphi_m(v_m) = 1 \). We define \( h_m \) to be the coefficient associated to \( f \cdot j^m \) and \( \varphi_m \). By all of the previous choices, \( |h_m(\gamma)| \leq |h_0(\gamma)| \), for all \( \gamma \in \Gamma \). As \( \sum_{\gamma \in \Gamma} |h_0(\gamma)| < \infty \) by Lemma 4.1, we obtain

\[
P_{h_m}(1) \to \sum_{\gamma \in \Gamma_0} \varphi(\gamma, v) = |\Gamma_0| \neq 0.
\]

By (4), we may choose an integer \( m \) big enough such that \( P_{h_m} \) is not identically zero. We denote again by \( P_{h_m} \) its canonical \( \mathbb{Z}_n \)-invariant extension to \( H(\mathbb{R})^+ \times J = G \cdot \mathbb{Z}_n \times J \).

Let \( f : H(A_Q) \to \mathbb{C} \) be the unique map which is \( H(\mathbb{Q}) \)-invariant on the left, zero outside \( H(\mathbb{Q}).(H(\mathbb{R})^+ \times J) \), and which coincides with \( P_{h_m} \) on the open subset \( H(\mathbb{R})^+ \times J \) (note that \( f \) is well defined). Then \( f \) is smooth, non-zero, and belongs to \( L^2(H(\mathbb{Q}) \backslash H(A_Q)/\mathbb{Z}_n, \mathbb{C}) \) by the estimate (3) (take \( U \) a measurable fundamental domain for \( \Gamma \) acting on \( G \times J \), they have finite volume). The closure of the \( H(A_Q) \)-subrepresentation generated by \( f \) is then a finite sum of topologically irreducible representations, any irreducible constituent \( \Pi \) of which satisfies the hypothesis of Proposition 4.1 by construction.

Remark. As shown by the proof above and by Lemma 4.2 below, we can even assume that the parameter \( \lambda \) of \( \Pi_\infty \) is as far from the walls of \( h^*_R \) as we want.

Lemma 4.2. Let \( \Gamma \) be a finite subgroup of a compact connected Lie group \( K \), and let \( \tau \) be an irreducible complex representation of \( \Gamma \). For any real \( C > 0 \), we can find an irreducible representation \( V \) of \( K \) such that \( V_\Gamma \) contains \( \tau \), and such that the highest weight of \( V \) has distance at least \( C \) from the walls.

Proof. Using character formulas of Weyl and Kostant, we could even prove that for a dominant weight \( \lambda \) far enough from the walls, \( (V_\lambda)_\Gamma \) contains \( \tau \) if and only if they have the same central character when restricted to \( \Gamma \). We thank Y. Benoist for explaining to us the following quick proof. We fix \( \mathfrak{h} \subset \mathfrak{k} \) a Cartan subalgebra, choose a Weyl chamber, and we denote by \( V_\lambda \) the complex irreducible representation of \( K \) of highest weight \( \lambda \in h^*_R \). By the Peter–Weyl theorem, we can find dominant weights \( \lambda_1, \ldots, \lambda_r \) such that \( W := \bigoplus_{i=1}^r V_{\lambda_i} \) contains, when restricted to \( \Gamma \), each irreducible finite-dimensional complex representation of \( \Gamma \). Let \( \lambda \) be any dominant weight, then the highest weights of \( V_\lambda \otimes C W \) lie in the ball of \( h^*_R \) centered in \( \lambda \) and of radius \( \sup_{i=1}^r |\lambda_i| \) (see [Kna86, ch. IV, § 11.13]). As \( \tau \otimes C W_{\Pi}^\ast \) contains all irreducible representations of \( \Gamma \) by construction, this concludes the proof.

5. The case \( E = \mathbb{Q} \)

The problematic in this section is the following: is it possible to reduce property \( P_{E,S,u} \) to some standard conjectures in the arithmetic theory of automorphic forms? To fix the ideas, we restrict to the case \( E = \mathbb{Q} \). As Proposition 4.1 does not apply to \( \text{GL}_n/\mathbb{Q} \) for \( n > 2 \), we must use other classical groups, which introduces some obstructions on the \( L \)-parameters we can reach with them. It turns out that admitting the (certainly believed!) Hypotheses 1 and 2 below, we can prove that \( P_{Q,\{\infty,l,p\},p} \) holds for any prime numbers \( l \neq p \), which is much stronger than Corollary 1.2. We end the section by discussing \( P_{Q,\{\infty,p\},p} \) for a prime number \( p \), which is the most interesting case in some sense, as its truth would imply all of the results of this paper.

5.1 Case \( S = \{\infty, l, p\}, p \neq l \) (proof of Theorem 1.2)

In this section, we give one way (certainly among many others) to deduce \( P_{Q,\{\infty,l,p\},p} \) from some expected properties of automorphic forms for the symplectic groups \( GSp_{2n}/\mathbb{Q} \) for all \( n \geq 2 \).
The proof is very similar to that of Theorem 1.1, so that we are rather sketchy on some points. Let \( \mathbb{Q}_{\text{ur}}^{\text{ab}} \subset \mathbb{Q}_p \) be the maximal abelian extension of \( \mathbb{Q}_p \), note that \( \mathbb{Q}_p^{\text{ur}} \subset \mathbb{Q}_{\text{ur}}^{\text{ab}} \).

**Proof of Theorem 1.2.** Let \( K/\mathbb{Q}_p \) be a finite Galois extension whose Galois group admits an injective irreducible representation \( \rho : \text{Gal}(K/\mathbb{Q}_p) \to \text{GL}_n(\mathbb{C}) \), we want to prove that \( K \subset \mathbb{Q}_p^{\text{ur}} \mathbb{Q}_{\{\infty,p\}} \).

The representation \( \rho \) extends to an irreducible \( L \)-parameter

\[
\psi : W_{\mathbb{Q}_p} \to \text{GL}_n(\mathbb{C}).
\]

Note that \( \mathbb{Q}_{\text{ur}}^{\text{ab}} \subset \mathbb{Q}_{\text{ur}}^{\text{ab}} \mathbb{Q}_{\{\infty,p\}} \) by local class field theory, hence we can replace \( \psi \) by any of its twists \( \psi' \) by a continuous character \( W_{\mathbb{Q}_p} \to \mathbb{C}^* \). We claim that for some well-chosen character, the dual of \( \psi' \) is not isomorphic to any unramified twist of \( \psi' \). Indeed, as \( \psi|_{\mathbb{Q}_p} \) has a finite image, we can find a \( g \in I_{\mathbb{Q}_p} \cap \text{Ker}(\psi) \) acting on \( \mathbb{Q}_p(\mu_{p\infty}) \) as an element of infinite order. We can then find a finite-order character \( \chi \) of \( \text{Gal}(\mathbb{Q}_p(\mu_{p\infty})/\mathbb{Q}_p) \) such that \( \chi^2(g) \neq 1 \). Hence, \( \psi' := \psi \otimes \chi \) does the trick as \( \text{tr}(\psi'(g)) = n\chi(g) \neq n\chi(g)^{-1} = \text{tr}(\psi^*(g)) \). We can therefore assume that \( \psi^* \) is not isomorphic to any unramified twist of \( \psi \).

Recall now that \( M := \text{GL}_n \times \text{GL}_1 \) is a Levi factor of the maximal parabolic subgroup of \( \text{GSp}_{2n} \) stabilizing a maximal isotropic subspace (the so-called Siegel parabolic). As the root datum of \( \text{GL}_n \times \text{GL}_1 \) is selfdual, \( \text{GL}_n(\mathbb{C}) \times \text{GL}_1(\mathbb{C}) \) is also a Levi subgroup of \( \text{GSp}_{2n} = \text{GSpin}_{2n+1}(\mathbb{C}) \). For any unramified characters \( \alpha, \beta : W_{\mathbb{Q}_p} \to \mathbb{C}^* \), we can thus consider the \( L \)-parameter

\[
\psi_{\alpha, \beta} := \psi \otimes \alpha \otimes \beta : W_{\mathbb{Q}_p} \to \text{GSpin}_{2n+1}(\mathbb{C}),
\]

deduced by functoriality. As \( \psi^* \) is not isomorphic to any unramified twist of \( \psi \), the centralizer of any \( \psi_{\alpha, \beta} \) in \( \text{GSpin}_{2n+1}(\mathbb{C}) \) is reduced to the center \( \mathbb{C}^* \times \mathbb{C}^* \) of \( \text{GL}_n(\mathbb{C}) \times \text{GL}_1(\mathbb{C}) \) (it obviously contains it). Indeed, if an element \( \gamma \in \text{GSpin}_{2n+1}(\mathbb{C}) \) satisfies \( \gamma \psi_{\alpha, \beta}(g) \gamma^{-1} = \psi_{\alpha, \beta}(g) \) for all \( g \in W_{\mathbb{Q}_p} \), its image \( \gamma \) in \( \text{PGSpin}_{2n+1}(\mathbb{C}) = \text{SO}_{2n+1}(\mathbb{C}) \) self-intertwines

\[
(\psi \otimes \alpha) \oplus (\psi \otimes \alpha)^* \oplus 1,
\]

and we conclude because this semi-simple representation is multiplicity free by assumption on \( \psi \). As a consequence, we expect that the hypothetical \( L \)-packet of \( \text{GSp}_{2n}(\mathbb{Q}_p) \) associated to any \( \psi_{\alpha, \beta} \) has only one element. Namely, if \( \pi_{\alpha, \beta} \) denotes the supercuspidal representation of \( M = \text{GL}_n(\mathbb{Q}_p) \times \text{GL}_1(\mathbb{Q}_p) \) attached to \( \psi \otimes \alpha \times \beta \) by Harris and Taylor, then the \( L \)-packet of \( \pi_{\alpha, \beta} \) should consist of the full\(^8\) normalized parabolic induction from \( M \) to \( \text{GSp}_{2n}(\mathbb{Q}_p) \) of \( \pi_{\alpha, \beta} \). We come now to our first hypothesis.

**Hypothesis 1.** For all supercuspidal representations \( \pi \) of \( \text{GL}_n(\mathbb{Q}_p) \) with no selfdual unramified twist, the inertial equivalence class \([M, \pi \times 1]_{\text{GSp}_{2n}(\mathbb{Q}_p)} \) admits a type in the sense of [BK98].

By the above hypothesis applied to \( \pi \times 1 \), and by Proposition 4.1, we can find a discrete, irreducible, automorphic representation \( \Pi \) of \( \text{GSp}_{2n}(\mathbb{A}_{\mathbb{Q}}) \) such that \( \Pi_l \) is unramified if \( l \notin \{\infty,p\} \), \( \Pi_p \in [M, \pi \times 1]_{\text{GSp}_{2n}(\mathbb{Q}_p)} \), and \( \Pi_{\infty} \) belongs to the holomorphic discrete series. Moreover, by the remark preceding Lemma 4.2, we may assume that the parameter \( \lambda \) of \( \Pi_{\infty} \) is far from the walls, hence \( \Pi \) should conjecturally belong to a tempered \( A \)-packet. Moreover, by the analysis preceding Hypothesis 1, the \( L \)-parameter \( \Psi_p \) of \( \Pi_p \) should have the form \( \psi_{\alpha, \beta} \) for some \( \alpha, \beta \). By replacing \( \Pi \) by an unramified twist if necessary, we may assume that \( \Pi_{\infty} \) is algebraic. Let us fix a complex injective representation \( r : \text{GSpin}_{2n+1}(\mathbb{C}) \to \text{GL}_{n_r}(\mathbb{C}) \), and embeddings \( \iota_l, \iota_{\infty} \) as in § 3.1. The reasoning above gives credit to the following.

---

\(^8\)This induced representation is known to be irreducible, see [Roc02].

1370
HYPOTHESIS 2. For some $r$ as above, there exists a continuous representation
\[ R : \text{Gal}(\mathbb{Q}_{(\infty,p,l)}/\mathbb{Q}) \rightarrow \text{GL}_{n_r}(\overline{\mathbb{Q}}_l), \]
such that the representation $\iota_\infty.t_1^{-1}.R|_{\mathbb{Q}_p} \simeq r \circ \Psi_p|_{\mathbb{Q}_p}$.

Of course, following Langlands, the hypothetical Galois representation $R$ associated to the automorphic representation $\Pi$, $\iota_\infty.t_1^{-1}$ and $r$, should satisfy this hypothesis. Assuming the above hypothesis, we obtain by the same reasoning as in the proof of Lemma 3.1(ii) that $\mathbb{Q}_p^ur.\mathbb{Q}_{(\infty,p,l)} \supset K$, which concludes the proof.

Remark 5.1. (i) Bushnell and Kutzko show in [BK98, §8] that Hypothesis 1 would follow from the existence of $\text{GSp}_{2n}(\mathbb{Q}_p)$-covers for the types they have constructed for the supercuspidal representations of $\text{GL}_n(\mathbb{Q}_p)$. Some of these covers have already been constructed by Blondel in [Blo04], but unfortunately only when $\tau$ has a selfdual unramified twist.

(ii) Hypothesis 2 is known for $n = 1$ (Carayol, Deligne, Langlands).

5.2 Case $l = p$
We would like to apply the same reasoning as in §5.1 to prove property $P_{\mathbb{Q}_{(\infty,p)},p}$, by choosing a $K$ as above and using $\Pi$, and this time using the hypothetical $p$-adic Galois representation $R$ attached to $\Pi$. The proof of §5.1 applies verbatim until the statement of Hypothesis 2, whose correct form becomes (II and $r$ are chosen as above) the following.

HYPOTHESIS 3. There exists a continuous representation
\[ R : \text{Gal}(\mathbb{Q}_{(\infty,p)}/\mathbb{Q}) \rightarrow \text{GL}_{n_r}(\overline{\mathbb{Q}}_p), \]
which is potentially semistable at $p$, and such that $\iota_\infty.t_1^{-1}.(R|_{\mathbb{Q}_p})_W^\Psi \simeq r \circ \Psi_p|_{\mathbb{Q}_p}$.

In the above statement, $\rho_W$ is the representation of $W_{\mathbb{Q}_p}$ attached by Fontaine to a $p$-adic $pst$ (i.e. potentially semistable) representation $\rho$ of $G_{\mathbb{Q}_p}$ (in fact, in the special situation above, the monodromy operator $N$ is automatically zero). Let $\rho := R|_{\mathbb{Q}_p}$. The last step to conclude would be to establish a link between $F_1 := \mathbb{Q}_p^ur.\varphi(\mathbb{Q}_{(\infty,p)}(R))$ and $F_2 := \mathbb{Q}_p^ur.\varphi(\mathbb{Q}_{(\infty,p)}(R))^W$ (which is $\mathbb{Q}_p^ur.\varphi(K$ in the notation of the proof of Theorem 1.2). Note that $F_1/\mathbb{Q}_p^ur$ (respectively $F_2$) is in general infinite (respectively always finite), it is the smallest algebraic extension (respectively finite Galois extension) of $\mathbb{Q}_p^ur$ over which $\rho$ becomes trivial (respectively semistable, even crystalline here). It turns out that it is not always the case that $F_2 \subset F_1$, which prevents us from concluding as before. We discuss this point in §5.3.

Remark 5.2. The ‘modular form case’ of Hypothesis 3 (i.e. $n = 1$) is known by the work of Carayol, Deligne, Langlands and Saito (see the main theorem in [Sai97]). In general, Hypothesis 3 would follow from Hypothesis 2, the construction of the pure motive attached to $\Pi$ and the conjectured independence of $l$ of the semisimplified Weil–Deligne representation associated to the $l$-adic cohomology of a given proper smooth scheme $X$ over $\mathbb{Q}_p$ (see [Fon94, §2.4.3]).

5.3 Kernels of $pst$ representations
Let $l \neq p$ be a prime number, we recall first the $l$-adic situation. Let $M/\mathbb{Q}_p$ be a local field. We fix a $\varphi \in W_M$ lifting a geometric Frobenius element, and a nonzero continuous homomorphism $t_l : I_M \rightarrow \mathbb{Q}_l$. Let $\rho : G_M \rightarrow \text{GL}_d(\overline{\mathbb{Q}}_l)$ be a continuous representation. By Grothendieck’s $l$-adic monodromy theorem, there exists a unique nilpotent matrix $N \in M_d(\overline{\mathbb{Q}}_l)$ such that $\rho$ and the representation of $I_M$ defined by $\gamma \mapsto \exp(t_l(\gamma)N)$ coincide on some open subgroup of $I_M$. 

1371
The Weil–Deligne representation attached to $\rho$ is then the isomorphism class of the pair $(\rho^W, N)$ where $\rho^W : \mathrm{W}_M \to \mathrm{GL}_d(\overline{\mathbb{Q}})$ is defined by (see [Tat79, §4.2] and [Fon94])

$$\rho^W(\varphi^n \gamma) := \rho(\varphi^n \gamma) \exp(-t_1(\gamma)N), \quad \gamma \in I_M, \ n \in \mathbb{Z}.$$ 

Note that $\rho^W|_{I_M}$ has finite image, hence consists of semisimple elements. In particular, $\mathrm{Ker}(\rho|_{I_M}) \subset \mathrm{Ker}(\rho^W|_{I_M})$, that is

$$M^\ur(\rho^W|_{I_M}) \subset M^\ur(\rho|_{I_M}).$$

Obviously, these inclusions are equality if and only if $N = 0$, that is $\rho = \rho^W$. We used implicitly this trivial fact in the proof of Lemma 3.1(ii).

Assume now that $l = p$, and that $\rho : G_M \to \mathrm{GL}(V)$ is a continuous representation on a finite-dimensional $\overline{\mathbb{Q}}_p$-vector space $V$, which is potentially semistable in the sense of Fontaine [Fon94]. It means that $D_{\mathrm{pst}}(V) := \bigcup_{L/K_{\text{finite}}} (V \otimes_{\mathbb{Q}_p} B_{st})^{GL}$ is free of rank $\dim_{\overline{\mathbb{Q}}_p}(V)$ over $\overline{\mathbb{Q}}_p \otimes_{\mathbb{Q}_p} \mathbb{Q}_p^{ur}$, where $B_{st}$ is the usual Fontaine ring. Fontaine defines then a representation, say $\rho^W$, of $\mathrm{W}_M$ on $D_{\mathrm{pst}}(V)$, whose restriction to $I_M$ is obvious. However, the analogue of the inclusion (5) is not always satisfied in this setting. We are grateful to P. Colmez and T. Saito for explaining to us the following example.

**Example.** Let $M := \mathbb{Q}_p$ and $K \subset \overline{\mathbb{Q}}_p$ be a finite extension of $\mathbb{Q}_p$. Let $\omega : G_K \to \overline{\mathbb{Q}}_p^*$ be a Lubin–Tate character of $K$, and $\psi : G_K \to \overline{\mathbb{Q}}_p$ be a continuous character of finite order on $I_K$, and $\chi := \omega \psi$. It is well known that $\omega$ is crystalline, hence $\chi$ is $\mathrm{pst}$, and the representation $\chi^W|_{I_K}$ on $D_{\mathrm{pst}}(\chi)$ is $\psi|_{I_K}$. Let $\rho := \mathrm{Ind}_{G_{\mathbb{Q}_p}}^{G_K} \chi$. An easy computation shows that $D_{\mathrm{pst}}(\rho) = \mathrm{Ind}_{\mathbb{W}_K}^{\mathbb{W}_M} D_{\mathrm{pst}}(\chi)$, hence $\rho$ is $\mathrm{pst}$ and $\rho^W = \mathrm{Ind}_{\mathbb{W}_K}^{\mathbb{W}_M} \chi^W$.

Let us assume from now that $K/\mathbb{Q}_p$ is Galois to simplify. Let $\mathrm{rec} : \mathcal{O}_K^* \to \mathcal{O}_K^{ab}$ be the reciprocity map of local classfield theory, recall that $\omega \circ \mathrm{rec}$ is the natural map $\mathcal{O}_K^* \to \mathcal{O}_K^{ab}$ induced by some field embedding $K \to \overline{\mathbb{Q}}_p$. We choose now $\psi$ such that $\psi \circ \mathrm{rec}$ is trivial on the pro-$p$-Sylow of $\mathcal{O}_K^*$, and coincides with $(\omega \circ \mathrm{rec})^{-1}$ on its $p'$-part. Then, $F_1 := \mathbb{Q}_p^{ur}(\rho^W)$ is the maximal, tamely ramified, abelian extension of $K$, and is linearly disjoint with $F_2 := \mathbb{Q}_p^{ur}(\rho)$ over $K^{ur}$. In particular, when $K/\mathbb{Q}_p$ is unramified of degree greater than one, it gives examples of $p$-adic $\mathrm{pst}$ representations $\rho$ of $G_{\mathbb{Q}_p}$ such that $\mathbb{Q}_p^{ab}(\rho^W)$ is not included in $\mathbb{Q}_p^{ab}(\rho)$.

**Remarks.** (i) We do not know whether there exists a strict subfield $L$ of $\overline{\mathbb{Q}}_p$ such that the inclusion (5) holds over $L$ for any $\rho$, or if (5) (or some variant) holds under a mild hypothesis on $\rho$. For our aim, the only controls we seem to have on $\rho$ are $\rho^W|_{I_M}$ and some information on its set of Hodge–Tate weights. What we do not control at all is the filtration data of $D_{\mathrm{pst}}(\rho)$. In this direction, we may hope that the $p$-adic Langlands philosophy initiated by Breuil will allow us, in the future, to use the Galois representations attached to $p$-adic automorphic forms, whose properties at $p$ are less restricted.

(ii) Assuming the extension of Saito’s theorem [Sai97] to Harris–Taylor’s automorphic forms, and using Corollary 4.1, a solution of the above problem of kernels would imply property $P_{E,\{\infty,u,u'\},u}$ where $E/\mathbb{Q}$ is a quadratic imaginary field and $p = uu'$ a prime number which splits in $E$. We mention this as the hypothesis we made in § 5.1 still seems to be out of reach (especially Hypothesis 2).

The author thanks J. Bellaïche, Y. Benoist, L. Clozel, P. Colmez, J.-F. Dat, L. Fargues, A. Genestier, M. Harris, G. Henniart, J.-P. Labesse, T. Saito, and K. Wingberg for their remarks or helpful discussions.

---

9It is, however, obviously satisfied when $\rho|_{I_M}$ has finite image, as $\rho^W = \rho|_{\mathrm{W}_M}$ in this case.
