visual hallucinosis are typical of the amphetamine psychosis first described by Connell (Maudsley Monograph 1958). This problem is a seriously underreported side-effect of such drugs, and highlights the need for extreme caution in their use.

The Place of Benzodiazepines in Psychiatric Practice

SIR: I am concerned that, in spite of the provisions mentioned, the paper on benzodiazepines by Tyrer & Murphy (Journal, December 1987, 151, 719–722) will, in effect make a further contribution towards inhibiting the judicious and careful use of these drugs in appropriate cases based on experienced clinical judgement. As the authors state, patients are already "being encouraged to sue doctors for making them dependent" (on benzodiazepines). A sense of proportion is surely required here.

There are still many patients with chronic anxiety symptoms who do not respond to expertly applied alternative therapeutic techniques and, especially if "over 50% can stop their medication without withdrawal problems" and "... from present evidence there is no unequivocal permanent handicap caused by benzodiazepines in short or long-term dosage", it seems to me that clinical psychiatrists should have the courage to publicise these points in a responsible manner so that the media in particular and the public in general are better informed on these important problems.

Heterogeneity in Sporadic Schizophrenia

SIR: Lewis et al (Journal, September 1987, 151, 306–314) have recently reviewed their original hypothesis (Murray et al, 1985) that the presence or absence of a family history identifies subgroups of greater aetiological homogeneity within schizophrenia. While their own data on ventricle brain ratios (VBR) in schizophrenic patients without a family history of major psychosis being larger than those with a family history (Reveley et al, 1984) are in support, results from other studies are not consistent...
