positioning, $P_{\text{peak}}$ increased to 40 cmH$_2$O and $\text{ETCO}_2$ increased to 45 mmHg. We could not pass a suction catheter beyond a distance of 24 cm from the entrance of the tracheal tube. Using a fibroscope, we could see the appearance of a meniscus and a crescent shape on the inner wall. Because of the prone position, we could not change the tube but managed to maintain ventilation, saturation and $\text{ETCO}_2$ within the normal range by a change of ventilatory mode for the remaining 5 h of the procedure. After returning to the supine position at the end of the operation, we extubated the patient and her self-respiration was good. Unfortunately, we found mild left lower lobe atelectasis post-operatively, which responded to physiotherapy. Her lung condition had returned to normal without complication by the second postoperative day.

Examination of the reinforced tube showed two internal blisters, one at the entrance and one at 24 cm from the entrance. Examination using a rigid fiberscope and computed tomography (Fig. 1) showed a dissection of the inner layer of the tube. The dissection had caused longitudinal blisters of 2.8 and 4.2 cm length and reduction of the internal diameter to 3.5 and 2.9 mm at the proximal and distal parts, respectively.

We assumed that the damage of the tube was caused by faulty manufacture. However, we subsequently discovered that the cause was multiple reuse of the single-use tube. Similar complications have been reported during anaesthesia with use of N$_2$O [2,3] or even without N$_2$O [4], exposure of heat, ethylene oxide [4–6] and gluteraldehyde solution [6] and stretching of a reinforced endotracheal tube [6]. The tube in this case had been cleaned after each use with hypochlorous acid (Medilox solution; Hicro-S®, Soosan GIC Co Ltd, Seoul, Korea) after ultrasonic cleansing for 30 min. We should bear in mind that repeated reuse of reinforced endotracheal tubes that are designed for single use is unwise.

Changes in renal function in valvular and coronary patients
doi: 10.1017/S0265021507001263

EDITOR:
I read with interest the article by Landoni and colleagues [1] regarding acute renal failure and mitral valve surgery. Acute renal failure is one of the most serious complications of cardiac surgery, with high morbidity and mortality, although the subject is still not completely understood. Most of the research related to valve surgery and cardio-

We agree with Landoni and colleagues that the risk for renal dysfunction and acute renal failure depends on many other factors: fasting, hypovolaemia, low cardiac output, emergencies, bleeding and preoperative renal dysfunction. Perioperative factors other than CPB should be considered the main reasons for acute renal failure in patients undergoing coronary and valvular surgery.

Effect of dexmedetomidine on blood pressure and bleeding in maxillo-facial surgery
doi: 10.1017/S0265021507001081

EDITOR:
We read with great interest the study report by Durmus and colleagues [1] concerning the effect of dexmedetomidine on bleeding during tympanoplasty or septrhinoplasty. The authors showed that, compared to placebo, dexmedetomidine decreased intraoperative mean arterial pressure (MAP), heart rate (HR) and bleeding in the surgical field.

In a similar prospective study, we have assessed the efficacy of dexmedetomidine in achieving controlled hypotension during maxillofacial surgery [2]. Twenty consecutive ASA I patients undergoing...
