In most cases admitted to the programme the psychological debriefing represents an immediate component which was neglected after traumatic exposure which permits secure retrieval of memory information and which facilitates the processing of the same.

Sir: Comparisons between the group treatment approach described by Busuttil et al (1995) for war veterans and the well documented Koach project (Solomon et al, 1992) highlight important treatment and research issues. The Koach project was a residential group treatment approach for PTSD developed to treat Israeli war veterans. Based on a behavioural model of PTSD, a central treatment component involved confronting anxiety using a number of behavioural techniques but there was “a deliberate refusal...to allow working through of past war experiences” (Shalev et al, 1992, p. 214). While subjective appraisal by therapists and the 41 participants was highly positive and therapeutic gains were shown in reducing phobias and improving social functioning, no improvement was noted in the symptoms of PTSD and at two year follow up the treatment group had a worse outcome than a no-treatment control group.

The Busuttil study in comparison incorporated no behavioural procedures directly aimed at anxiety habituation and extinction and the focus of therapy was the “psychological debriefing” or information processing component. It is necessary to acknowledge possible group differences, the methodological flaws of the studies, the possibility that the Israeli study may not have ensured that habituation of anxiety accompanied exposure and that debriefing did allow for some habituation of anxiety. Nonetheless, the high success rate in reducing PTSD symptoms such that 85.3% no longer satisfied the criteria for diagnosis of PTSD is in marked contrast to the Israeli findings.

It has been questioned whether information-processing models of PTSD add anything to Pavlovian models of extinction (Hacker-Hughes & Thompson, 1994). Richards & Rose (1991) found in a study which looked at imaginal exposure and in vivo exposure, that “where in vivo exposure was tried first, it was either ineffective or only partially effective” (p. 839). In a study of an implosion treatment with rape survivors, Foa et al (1995) also present findings showing that successful outcome was associated with changes in subjects’ rape narratives suggestive of information processing of the event. In the same article Foa quotes other authors who conclude that for trauma survivors, the need to make sense of their traumatic experience is of vital importance.

Much of the treatment literature in PTSD has a behavioural or cognitive-behavioural bias. Such approaches have proved valuable but other theoretical models may have the potential to enhance both the understanding of PTSD and therapeutic effectiveness.

Psychiatric morbidity in rural v. urban regions

Sir: Mumford et al (1996) showed that women in Chitral, Pakistan, suffered surprisingly more anxiety and depressive disorders than their counterparts in Western countries. This finding contradicts the common belief that people who live in remote rural areas of the globe, being exempt from the pressure of civilization, lead relatively stress-free lives. However, it is not so surprising when one considers that socioeconomic and political changes have negatively impinged on the livelihood of rural people and aggravated their powerlessness in many developing countries nowadays (Desjarlais et al, 1995).
Contemporary China furnishes a good example. Compared with the rapid development in big cities and in the commercial and industrial sectors of the coastal areas, a combination of adverse factors, including a low income growth rate, heavy tax burdens and surplus labour have hindered economic development, intensified poverty, and threatened social stability in rural China, which is inhabited by a staggering 900 million population (Liu, 1995). Along with gender inequalities and the one-child-per-couple policy adopted since 1980, these social forces have underprivileged rural women. Although the one child policy is responsible for China’s remarkable success in population control and is relatively well accepted by urban couples, it drastically clashes with the entrenched value of duo zi duo sun ("having more sons and grandsons"), which is integral to agrarian subsistence and rural women’s social status. Ethnographic studies revealed that women who gave birth to baby girls were fearful about not carrying on the lineage, the loss of extra labour power, and not having someone to provide for them in old age. They experienced a loss of face, alienation, and often physical abuse (Pearson, 1995). In such an oppressive context, depressive and anxiety disorders may also be understandable reactions to the brutality of everyday deprivation that will respond less to psychotropic agents than socially meaningful forms of empowerment.

Lithium revisited

SIR: I am pleased that my editorial (Moncrieff, 1995) has provoked some discussion but I do not believe that I made any erroneous statements about Coppen et al’s (1971) trial (Coppen, 1996). The paper presented results for 65 patients but only 37 of these had bipolar disorder and the number of subjects who did not complete the first 16 weeks of treatment was not documented in the original report. I criticised the study for failing to do an “intention to treat” analysis as the comparability of the residual groups cannot be assumed. The presentation of results was also unsatisfactory with no information on the number or polarity of episodes and global assessment scores combined in various ways that were not specified a priori. In addition diagnosis of illness episodes and administration of additional treatments may have been influenced by unblinding effects, emphasised again by Double (1996). Meta-analysis with the trials I reviewed would only reflect and amplify previous problems.

The follow up study cited (Fieve et al, 1976), which concerned a mixed group of bipolar and unipolar patients taking lithium did not demonstrate unequivocal success. Fourteen per cent of patients were admitted during the course of one year, 20% were prescribed neuroleptics and 37% antidepressants and it is likely that rates of morbidity were higher in the bipolar group, which was not examined separately (Coppen & Abou-Saleh, 1988).

Minor physical and factual anomalies

SIR: In their article on minor physical anomalies (MPAs) and schizophrenia, Murphy & Owen (1996) state

"The majority of proponents of the neurodevelopmental model have focused on an environmental rather than a genetic explanation for the excess of MPAs seen in schizophrenia (Mednick et al, 1988; Murray et al, 1992)."

In fact, my views are not those Murphy & Owen attribute to me and the paper they quote contains no statement regarding the causes of MPAs. Elsewhere, in an article which was entitled “The genetics of schizophrenia is the genetics of neurodevelopment”, we (Jones & Murray, 1991) wrote:
