STRONG CONVERGENCE THEOREMS FOR FIXED POINTS OF PSEUDO-CONTRACTIVE SEMIGROUP

XUE-SONG LI AND NAN-JING HUANG

1. INTRODUCTION

Let $E$ be a real Banach space with the dual space $E^*$ and $J : E \to 2^{E^*}$ be a normalised duality mapping defined by

$$J(x) = \{ x^* \in E^* : \langle x, x^* \rangle = \| x \|^2 = \| x^* \|^2 \},$$

where $\langle \cdot, \cdot \rangle$ denotes the generalised duality pairing. It is well known that (see, for example, [10, pp. 107–113])

(i) $J$ is single-valued if $E^*$ is strictly convex;

(ii) $E$ is uniformly smooth if and only if $J$ is single-valued and uniformly continuous on any bounded subset of $E$.

Let $K$ be a nonempty closed convex subset of $E$. A mapping $T : K \to K$ is said to be

(i) nonexpansive if

$$\| Tx - Ty \| \leq \| x - y \|, \quad \forall x, y \in K;$$
(ii) \(L\)-Lipschitzian if there exists a constant \(L > 0\) such that
\[
\|Tx - Ty\| \leq L\|x - y\|, \quad \forall x, y \in K;
\]

(iii) strongly pseudo-contractive if there exist a constant \(\alpha \in (0,1)\) and \(j(x - y) \in J(x - y)\) such that
\[
\langle Tx - Ty, j(x - y) \rangle \leq \alpha \|x - y\|^2, \quad \forall x, y \in K;
\]

(iv) pseudo-contractive if there exists \(j(x - y) \in J(x - y)\) such that
\[
\langle Tx - Ty, j(x - y) \rangle \leq \|x - y\|^2, \quad \forall x, y \in K.
\]

Obviously, the mapping \(T\) is pseudo-contractive if and only if the mapping \(A = I - T\) is accretive on \(K\), where \(I\) is an identity mapping (see [2, 4]); pseudo-contractive mappings are more general than nonexpansive mappings.

A pseudo-contractive semigroup is a family
\[
\Gamma := \{T(t) : t \geq 0\}
\]
of self-mappings on \(K\) such that
\begin{enumerate}
\item \(T(0)x = x\) for all \(x \in K\);
\item \(T(s + t)x = T(s)T(t)x\) for all \(x \in K\) and \(s, t \geq 0\);
\item \(T(t)\) is pseudo-contractive for each \(t \geq 0\);
\item for each \(x \in K\), the mapping \(T(\cdot)x\) from \(R^+\) into \(K\) is continuous.
\end{enumerate}

If the mapping \(T(t)\) in condition (3) is replaced by
\[(3') \quad T(t)\text{ is nonexpansive for each } t \geq 0;
\]
then \(\Gamma := \{T(t) : t \geq 0\}\) is said to be a nonexpansive semigroup on \(K\).

We denote by \(F(\Gamma)\) the common fixed point set of a pseudo-contractive semigroup \(\Gamma\); that is,
\[
F(\Gamma) = \cap_{t \in R^+} F(T(t)) = \{x \in K : T(t)x = x \text{ for each } t \geq 0\}.
\]

In the sequel, we always assume \(F(\Gamma) \neq \emptyset\).

Let \(T\) be a nonexpansive mapping from \(K\) into itself. For any given \(u \in K\) and each \(t \in (0, 1)\), it follows from Banach’s fixed theorem that the following implicit iteration process is well defined:
\[
(1.1) \quad x_t = tu + (1 - t)Tx_t
\]

Browder [1] (Reich [8], respectively) proved that as \(t \to 0\), \(x_t\) converges strongly to some fixed point of \(T\) in Hilbert space (uniformly smooth Banach space, respectively).
An interesting work is to extend Browder's and Reich's results to semigroups. Recently, Suzuki [9] firstly introduced and studied the following implicit iteration sequence constructed from a nonexpansive semigroup in Hilbert space, for any given \( u \in K \),

\[
(1.2) \quad x_n = \alpha_n u + (1 - \alpha_n)T(t_n)x_n, \quad \forall n \geq 1,
\]

where \( \alpha_n \in (0,1) \), and obtained the convergence theorem under certain appropriate assumptions imposed on the parameters \( \{\alpha_n\} \) and \( \{t_n\} \). Very recently, Xu [12] studied the convergence of (1.2) in a uniformly convex Banach space with a weakly continuous duality mapping and obtained some convergence theorems for nonexpansive semigroup as follows:

**Theorem X.** ([12]) Let \( E \) be a uniformly convex Banach space having a weakly continuous duality map \( J_\varphi \) with gauge \( \varphi \), \( K \) a nonempty closed convex subset of \( E \) and

\[
\Gamma := \{T(t) : t \geq 0\}
\]

a nonexpansive semigroup on \( K \) such that \( \text{Fix}(\Gamma) \neq \emptyset \). If

\[
\lim_{n \to \infty} t_n = \lim_{n \to \infty} \frac{\alpha_n}{t_n} = 0,
\]

then \( \{x_n\} \) generated by (1.2) converges strongly to a member of \( F \).

Xu [12] also proposed the following problem:

**Problem X.** ([12]) We do not know if Theorem X holds in a uniformly convex and uniformly smooth Banach space (for example, \( L^p \) for \( 1 < p < \infty \)).

On the other hand, Xu and Ori [13] introduced the following implicit iteration process constructed from a finite family of nonexpansive mappings in Hilbert space, for any given \( x_0 \in K \),

\[
(1.3) \quad x_n = \alpha_n x_{n-1} + (1 - \alpha_n)T_nx_n, \quad \forall n \geq 1,
\]

where \( T_n = T_n(\mod N) \) and \( \alpha_n \in (0,1) \). Furthermore, Osilike [6] extended the results of Xu and Ori [13] from the class of nonexpansive mappings to the more general class of Lipschitzian pseudo-contractive mappings.

It is also an interesting work to extend Osilike's results to semigroup. Thus, we introduce the following implicit iteration process constructed from a pseudo-contractive semigroup \( \Gamma := \{T(t) : t \geq 0\} \) in a real Banach space, for any given \( x_0 \in K \),

\[
(1.4) \quad x_n = \alpha_n x_{n-1} + (1 - \alpha_n)T(t_n)x_n, \quad \forall n \geq 1,
\]

where \( T(t_n) \in \Gamma \) and \( \alpha_n \in (0,1) \).

In this paper, we study the convergence of the implicit iteration process (1.2) constructed from the pseudo-contractive semigroup \( \Gamma := \{T(t) : t \in \mathbb{R}^+\} \) in uniformly convex...
Banach spaces with uniformly Gâteaux differential norms. As a special case, we obtain the convergence of the implicit iteration process for approximating the common fixed point of the nonexpansive semigroup in uniformly smooth Banach spaces, which gives a positive answer to Problem X proposed by Xu [12]. We also study the convergence of the implicit iteration process (1.4) constructed from the pseudo-contractive semigroup \( \Gamma \) in uniformly convex Banach spaces with uniformly Gâteaux differential norms. The results presented in this paper generalise some corresponding results in [6, 9, 12].

2. Preliminaries

A real Banach space \( E \) is said to have a weakly continuous duality mapping if \( J \) is single-valued and weak-to-weak* sequentially continuous (that is, if each \( \{x_n\} \) is a sequence in \( E \) weakly convergent to \( x \), then \( \{J(x_n)\} \) converges weakly* to \( J(x) \)). Obviously, if \( E \) has a weakly continuous duality mapping, then \( J \) is norm-to-weak* sequentially continuous. It is well known that \( l^p \) (\( 1 < p < \infty \)) possesses duality mapping which is weakly continuous (see, for example, [12]).

Let \( l^\infty \) be the Banach space of all bounded real-valued sequences. A Banach limit \( \text{LIM} \) (see [10]) is a linear continuous functional on \( l^\infty \) such that

\[
\| \text{LIM} \| = \text{LIM}(1) = 1, \quad \text{LIM}(t_1, t_2, \ldots) = \text{LIM}(t_2, t_3, \ldots)
\]

for each \( t = (t_1, t_2, \ldots) \in l^\infty \). If \( \text{LIM} \) is a Banach limit, then it follows from [10, Theorem 1.4.4] that

\[
\liminf_{n \to \infty} t_n \leq \text{LIM}(t) \leq \limsup_{n \to \infty} t_n
\]

for each \( t = (t_1, t_2, \ldots) \in l^\infty \).

A Banach space \( E \) is said to satisfy Opial's condition if whenever \( \{x_n\} \) is a sequence in \( E \) which converges weakly to \( x \), then

\[
\limsup_{n \to \infty} \|x_n - x\| < \limsup_{n \to \infty} \|x_n - y\|
\]

for all \( y \in E \) with \( y \neq x \). It is well known that every Hilbert space satisfies the Opial's condition (see, for example, [5]).

A mapping \( T \) with domain \( D(T) \) and range \( R(T) \) in \( E \) is said to be demiclosed at a point \( p \in E \) if whenever \( \{x_n\} \) is a sequence in \( D(T) \) which converges weakly to \( x \in D(T) \) and \( \{Tx_n\} \) converges strongly to \( p \), then \( Tx = p \).

For the sake of convenience, we restate the following lemmas that shall be used.

**Lemma 2.1.** ([3]) Let \( E \) be a Banach space, \( K \) be a nonempty closed convex subset of \( E \) and \( T : K \to K \) be a strongly pseudo-contractive and continuous mapping. Then \( T \) has a unique fixed point in \( K \).
LEMMA 2.2. ([7]) Let $E$ be a Banach space and $J$ be the normalised duality mapping. Then for any $x, y \in E$ and $j(x + y) \in J(x + y)$,

$$
\|x + y\|^2 \leq \|x\|^2 + 2\langle y, j(x + y) \rangle.
$$

LEMMA 2.3. ([13]) Let $\tau > 0$. Then a real Banach space $E$ is uniformly convex if and only if there exists a continuous and strictly increasing convex function $g : [0, \infty) \to [0, \infty)$ with $g(0) = 0$ such that

$$
\|\lambda x + (1 - \lambda)y\|^2 \leq \lambda\|x\|^2 + (1 - \lambda)\|y\|^2 - \lambda(1 - \lambda)g(\|x - y\|)
$$

for all $x, y \in B_\tau$, $\lambda \in [0, 1]$, where $B_\tau = \{x \in E : \|x\| \leq \tau\}$.

3. MAIN RESULTS

We first discuss the convergence of implicit iteration process (1.2) constructed from a pseudo-contractive semigroup $\Gamma := \{T(t) : t \geq 0\}$.

**Theorem 3.1.** Let $K$ be a nonempty closed convex subset of a real Banach space $E$ and $\Gamma := \{T(t) : t \in \mathbb{R}^+\}$ be a strongly continuous $L$-Lipschitzian semigroup of pseudo-contractive mappings. Then the sequence $\{x_n\}$ generated by (1.2) is well defined. Moreover, if

$$
\lim_{n \to \infty} t_n = \lim_{n \to \infty} \frac{\alpha_n}{t_n} = 0,
$$

then $\lim_{n \to \infty} \|x_n - T(t)x_n\| = 0$ for any $t \in \mathbb{R}^+$.

**Proof:** Let

$$
T_n x := \alpha_n u + (1 - \alpha_n)T(t_n)x, \quad \forall n \geq 1.
$$

Since

$$
\langle T_n x - T_n y, j(x - y) \rangle = (1 - \alpha_n)\langle T(t_n)x - T(t_n)y, j(x - y) \rangle 
\leq (1 - \alpha_n)\|x - y\|^2,
$$

we know that $T_n$ is strongly pseudo-contractive and strongly continuous. It follows from Lemma 2.1 that $T_n$ has a unique fixed point (say) $x_n \in K$, that is, $\{x_n\}$ generated by (1.2) is well defined.

Taking $p \in F(\Gamma)$, we have

$$
\|x_n - p\|^2 = \alpha_n \langle u - p, j(x_n - p) \rangle + (1 - \alpha_n)\langle T(t_n)x_n - T(t_n)p, j(x_n - p) \rangle 
\leq \alpha_n \|u - p\| \|j(x_n - p)\| + (1 - \alpha_n)\|x_n - p\|^2 
= \alpha_n \|u - p\| \|x_n - p\| + (1 - \alpha_n)\|x_n - p\|^2.
$$
and so \( \|x_n - p\| \leq \|u - p\| \). This means \( \{x_n\} \) is bounded. By the Lipschitzian condition of \( \Gamma \), it follows that \( \{T(t_n)x_n\} \) is bounded. Therefore,

\[
\|x_n - T(t_n)x_n\| = \alpha_n\|u - T(t_n)x_n\| \to 0.
\]

For any given \( t > 0 \),

\[
\|x_n - T(t)x_n\| = \sum_{k=0}^{[t/t_n]-1} \left\|T\left(k(t_n)\right)x_n - T\left(k(t_n)t_n\right)x_n\right\| + \left\|T(t)x_n - T\left([t/t_n]t_n\right)x_n\right\|
\]

\[
\leq \left\lfloor t/t_n \right\rfloor L\|x_n - T(t_n)x_n\| + L\|T(t - \left\lfloor t/t_n \right\rfloor t_n)x_n - x_n\|
\]

\[
\leq tL\frac{\alpha_n}{t_n}\|u - T(t_n)x_n\| + L\max\left\{\|T(s)x_n - x_n\| : 0 \leq s \leq t_n\right\},
\]

where \([t/t_n] \) is the integral part of \( t/t_n \). Since \( \lim_{n \to \infty} \alpha_n/t_n = 0 \) and \( T(\cdot)x : R^+ \to K \) is continuous for any \( x \in K \), we have

\[
\lim_{n \to \infty} \|x_n - T(t)x_n\| = 0.
\]

This completes the proof.

**Theorem 3.2.** Let \( E \) be a uniformly convex Banach space with the uniformly Gâteaux differential norm and \( K \) be a nonempty closed convex subset of \( E \). Let \( \Gamma := \{T(t) : t \in R^+\} \) be a strongly continuous \( L \)-Lipschitzian semigroup of pseudo-contractive mappings and \( \{x_n\} \) be generated by (1.2). If the following conditions hold:

1. \( \lim_{n \to \infty} (\alpha_n/t_n) = \lim_{n \to \infty} t_n = 0; \)
2. \( \lim \|T(t)x_n - T(t)x^*\| \leq \lim \|x_n - x^*\|, \forall x^* \in C, t \in R^+ \),

where

\[
C := \{x^* \in K : \Phi(x^*) = \min_{x \in K} \Phi(x)\}
\]

with \( \Phi(x) = \lim_{n \to \infty} \|x_n - x\|^2 \) for all \( x \in K \);

then \( \{x_n\} \) converges strongly to a member of \( F(\Gamma) \).

**Proof:** From Theorem 3.1, we know that \( \{x_n\} \) is bounded and \( \lim_{n \to \infty} \|x_n - T(t)x_n\| = 0 \). It is easy to see that \( C \) is a nonempty bounded closed convex subset of \( K \) (see, for example [11]).

Now, we show that there exists a common fixed point of \( \Gamma \) in \( C \). For any \( t \in R^+ \) and \( x^* \in C \), it follows from \( \lim_{n \to \infty} \|x_n - T(t)x_n\| = 0 \) that

\[
\Phi(T(t)x^*) = \lim \|x_n - T(t)x^*\|^2
\]

\[
= \lim \|T(t)x_n - T(t)x^*\|^2
\]

\[
\leq \lim \|x_n - x^*\|^2
\]

\[
= \Phi(x^*)
\]
and so

\[(3.2) \quad T(t)(C) \subset C.\]

Next, we prove that $C$ is a singleton. In fact, since $E$ is uniformly convex, by Lemma 2.3 that there exists a continuous and strictly increasing convex function $g : [0, \infty) \to [0, \infty)$ with $g(0) = 0$ such that, for any $x_1^* \in C,$

\[\|x_n - \frac{x_1^* + x_2^*}{2}\|^2 \leq \frac{1}{2}\|x_n - x_1^*\|^2 + \frac{1}{2}\|x_n - x_2^*\|^2 - \frac{1}{4}g(\|x_1^* - x_2^*\|).\]

Taking Banach limit $\lim$ on the above inequality, it follows that

\[\frac{1}{4}g(\|x_1^* - x_2^*\|) \leq \frac{1}{2}\lim\|x_n - x_1^*\|^2 + \frac{1}{2}\lim\|x_n - x_2^*\|^2 - \lim\|x_n - \frac{x_1^* + x_2^*}{2}\|^2 \leq 0.\]

This implies $x_1^* = x_2^*$ and so $C$ is a singleton. Therefore, (3.2) implies that there exists $x^* \in C$ such that $x^* \in F(\Gamma)$.

For any $p \in F(\Gamma)$, from (1.2), we have

\[\langle x_n - u, j(x_n - p) \rangle = \frac{1 - \alpha_n}{\alpha_n} \langle T(t_n)x_n - x_n, j(x_n - p) \rangle = \frac{1 - \alpha_n}{\alpha_n} \left[\langle T(t_n)x_n - T(t_n)p, j(x_n - p) \rangle - \langle x_n - p, j(x_n - p) \rangle \right] \leq 0.\]

(3.3)

Since $x^* \in F(\Gamma)$, it follows from (3.3) that

\[(3.4) \quad \lim\langle x_n - u, j(x_n - x^*) \rangle \leq 0.\]

Furthermore, for any $t \in (0,1)$, by Lemma 2.2, we have

\[\|x_n - x^* - t(u - x^*)\|^2 \leq \|x_n - x^*\|^2 - 2t \langle u - x^*, j(x_n - x^* - t(u - x^*)) \rangle \leq \|x_n - x^*\|^2 - 2t \langle u - x^*, j(x_n - x^*) \rangle - 2t \langle u - x^*, j(x_n - x^* - t(u - x^*)) - j(x_n - x^*) \rangle \]

and

\[\langle u - x^*, j(x_n - x^*) \rangle \leq \frac{1}{2t} \left[\|x_n - x^*\|^2 - \|x_n - x^* - t(u - x^*)\|^2 \right] - \langle u - x^*, j(x_n - x^* - t(u - x^*)) - j(x_n - x^*) \rangle.\]

For any $\varepsilon > 0$, since $E$ has a uniformly Gâteaux differential norm, we know that $J$ is norm-to-weak* uniformly continuous on any bounded subset of $E$ (see, for example, [10, pp.107-113]) and so there exists sufficient small $\delta(\varepsilon) > 0$ such that

\[\langle u - x^*, j(x_n - x^*) \rangle \leq \frac{1}{2t} \left[\|x_n - x^*\|^2 - \|x_n - x^* - t(u - x^*)\|^2 \right] + \varepsilon, \quad \forall t \in (0, \delta).\]
This implies that
\[ \lim \langle u - x^*, j(x_n - x^*) \rangle \leq \frac{1}{2t} \left[ \lim \| x_n - x^* \|^2 - \lim \| x_n - x^* - t(u - x^*) \|^2 \right] + \varepsilon < \varepsilon. \]
By the arbitrariness of \( \varepsilon \), it follows that
\[ \lim \langle u - x^*, j(x_n - x^*) \rangle \leq 0. \]
Adding inequalities (3.4) and (3.5), we have
\[ \lim \langle x_n - x^*, j(x_n - x^*) \rangle = \lim \| x_n - x^* \|^2 \leq 0. \]
This implies that there exists subsequence \( \{x_{n_j}\} \subset \{x_n\} \) which converges strongly to \( x^* \). From the proof of (3.6), we know that \( \lim \| x_{n_j} - x^* \|^2 \leq 0 \) for any subsequence \( \{x_{n_j}\} \subset \{x_n\} \) and so there exists subsequence of \( \{x_{n_j}\} \) which converges strongly to \( x^* \). If there exists another subsequence \( \{x_{n_k}\} \subset \{x_n\} \) which converges strongly to \( y^* \), then it follows from Theorem 3.1 that \( y^* \in F(\Gamma) \). From (3.3), we have
\[ \langle x^* - u, j(x^* - y^*) \rangle \leq 0, \quad \langle y^* - u, j(y^* - x^*) \rangle \leq 0. \]
This implies that \( \| x^* - y^* \|^2 \leq 0 \) and so \( x^* = y^* \). Therefore, \( \{x_n\} \) converges strongly to \( x^* \in F(\Gamma) \). This completes the proof.

If \( \Gamma := \{ T(t) : t \in \mathbb{R}^+ \} \) is a nonexpansive semigroup, then \( \Gamma := \{ T(t) : t \in \mathbb{R}^+ \} \) is a strongly continuous \( L \)-Lipschitzian semigroup of pseudo-contractive mappings. From Theorem 3.2, we have the following result.

**Corollary 3.1.** Let \( E \) be a uniformly convex Banach space with the uniformly Gâteaux differential norm and \( K \) be a nonempty closed convex subset of \( E \). Let \( \Gamma := \{ T(t) : t \in \mathbb{R}^+ \} \) be a nonexpansive semigroup and \( \{x_n\} \) be generated by (1.2). If
\[ \lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0, \]
then \( \{x_n\} \) converges strongly to a member of \( F(\Gamma) \).

**Remark 3.1.** If \( E \) is a uniformly smooth Banach space, then \( E \) has the uniformly Gâteaux differential norm. Thus, Corollary 3.1 gives a positive answer to Problem X proposed by Xu [12].

**Theorem 3.3.** Let \( E \) be a uniformly smooth Banach space and \( K \) be a nonempty closed convex subset of \( E \). Let \( \Gamma := \{ T(t) : t \in \mathbb{R}^+ \} \) be a nonexpansive semigroup and \( \{x_n\} \) be generated by (1.2). If
\[ \lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0, \]
then \( \{x_n\} \) converges strongly to a member of \( F(\Gamma) \).
PROOF: For the nonexpansive semigroup $\Gamma$, condition (2) of Theorem 3.2 is trivial and so formula (3.2) holds. Since uniformly smooth Banach space $E$ has the fixed point property for nonexpansive mapping $T(t)$ (see, for example, [11]), $T(t)$ has a fixed point $x^* \in C \cap F(\Gamma)$. The rest proof is similar to the proof of Theorem 3.2 and so we omit it. This completes the proof.

REMARK 3.2. Theorem 3.3 gives a positive answer to Problem X proposed by Xu [12] in a uniformly smooth Banach space $E$ without the uniform convexity.

THEOREM 3.4. Let $E$ be a real Hilbert space and $K$ be a nonempty closed convex subset of $E$. Let $\Gamma := \{T(t) : t \in R^+\}$ be a strongly continuous $L$-Lipschitzian semigroup of pseudo-contractive mappings and $\{x_n\}$ be generated by (1.2). If

$$\lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0,$$

then $\{x_n\}$ converges strongly to a member of $F(\Gamma)$.

PROOF: From the proof of Theorem 3.1, we know that $\{x_n\}$ is bounded and so there exists subsequence $\{x_{n_j}\} \subset \{x_n\}$ which converges weakly to some point $x^* \in K$. By Theorem 3.1, we have

$$\lim_{n \to \infty} \|x_n - T(t)x_n\| = 0.$$

It follows from [2, Theorem 3.18b] that $I - T(t)$ is demiclosed at zero for each $t \in R^+$, where $I$ is an identity mapping. This implies that $x^* \in F(\Gamma)$.

In addition, from (1.2), we have

$$\|x_n - x^*\|^2 = \alpha_n \langle u - x^*, x_n - x^* \rangle + (1 - \alpha_n) \langle T(t_n)x_n - x^*, x_n - x^* \rangle \leq \alpha_n \langle u - x^*, x_n - x^* \rangle + (1 - \alpha_n) \|x_n - x^*\|^2,$$

and so

$$\|x_n - x^*\|^2 \leq \langle u - x^*, x_n - x^* \rangle.$$

This implies that $\{x_{n_j}\}$ converges strongly to $x^* \in F(\Gamma)$. Similar to the proof of Theorem 3.2, it is easy to show that $\{x_n\}$ converges strongly to $x^* \in F(\Gamma)$. This completes the proof.

REMARK 3.3. Theorem 3.4 extends the results of Suzuki [9] and Xu [12] from nonexpansive semigroup to pseudo-contractive semigroup in real Hilbert spaces.

Now we turn to discuss the convergence of implicit iteration process (1.4) for approximating the common fixed point of the pseudo-contractive semigroup $\Gamma := \{T(t) : t \geq 0\}$.

THEOREM 3.5. Let $K$ be a nonempty closed convex subset of a real Banach space $E$ and $\Gamma := \{T(t) : t \in R^+\}$ be a strongly continuous $L$-Lipschitzian semigroup of
pseudo-contractive mappings. Then the sequence \( \{x_n\} \) generated by (1.4) is well defined. Moreover, if \[ \lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0, \]
then \[ \lim_{n \to \infty} \|x_n - T(t)x_n\| = 0 \]
for any \( t \in R^+ \) and \( \lim \|x_n - p\| \) exists for any \( p \in F(\Gamma) \). Furthermore, if \( E \) is a uniformly convex Banach space with the uniformly Gâteaux differential norm and condition (2) of Theorem 3.2 holds, then \( \{x_n\} \) converges strongly to a member of \( F(\Gamma) \).

PROOF: Let
\[ T_n x := \alpha_n x_{n-1} + (1 - \alpha_n)T(t_n)x, \quad \forall n \geq 1. \]

It is obvious that \( T_n \) is strongly pseudo-contractive and strongly continuous. From Lemma 2.1, it is easy to know that \( \{x_n\} \) generated by (1.4) is well defined.

Taking \( p \in F(\Gamma) \), it follows that
\[
\|x_n - p\|^2 = \alpha_n \langle x_{n-1} - p, j(x_n - p) \rangle + (1 - \alpha_n) \langle T(t_n)x_n - T(t_n)p, j(x_n - p) \rangle \\
\leq \alpha_n \|x_{n-1} - p\| \|j(x_n - p)\| + (1 - \alpha_n) \|x_n - p\|^2 \\
= \alpha_n \|x_{n-1} - p\| \|x_n - p\| + (1 - \alpha_n) \|x_n - p\|^2
\]
and so \( \|x_n - p\| \leq \|x_{n-1} - p\| \). This means \( \lim_{n \to \infty} \|x_n - p\| \) exists for any \( p \in F(\Gamma) \). Similar to the proof of Theorem 3.1, we have \( \lim_{n \to \infty} \|x_n - T(t)x_n\| = 0 \) for any \( t \in R^+ \).

From (1.4) and (3.4), for any \( x^* \in C \cap F(\Gamma) \), we have
\[
\text{LIM}\langle x_n - x_{n-1}, j(x_n - x^*) \rangle \leq 0.
\]

Since \( \|x_n - p\| \leq \|x_{n-1} - p\| \), we know that \( \{x_n\} \) is bounded. Similar to the proof of (3.5), we have
\[
\text{LIM}\langle x_{n-1} - x^*, j(x_n - x^*) \rangle \leq 0.
\]

Adding inequalities (3.7) and (3.8), we get
\[
\text{LIM}\langle x_n - x^*, j(x_n - x^*) \rangle = \text{LIM}\|x_n - x^*\|^2 \leq 0.
\]

This implies that there exists subsequence \( \{x_{n_j}\} \subset \{x_n\} \) which converges strongly to \( x^* \). Since \( \lim_{n \to \infty} \|x_n - x^*\| \) exists, it follows that \( \{x_n\} \) converges strongly to \( x^* \in F(\Gamma) \). This completes the proof.

If \( \Gamma := \{T(t) : t \in R^+\} \) is a nonexpansive semigroup, then \( \Gamma := \{T(t) : t \in R^+\} \) is a strongly continuous \( L \)-Lipschitzian semigroup of pseudo-contractive mappings. Therefore, Theorem 3.5 gives the following result.
**Corollary 3.2.** Let $E$ be a uniformly convex Banach space with the uniformly Gâteaux differential norm and $K$ be a nonempty closed convex subset of $E$. Let $\Gamma := \{T(t) : t \in R^+\}$ be a nonexpansive semigroup and $\{x_n\}$ be generated by (1.4). If

$$\lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0,$$

then $\{x_n\}$ converges strongly to a member of $F(\Gamma)$.

**Theorem 3.6.** Let $E$ be a uniformly smooth Banach space and $K$ be a nonempty closed convex subset of $E$. Let $\Gamma := \{T(t) : t \in R^+\}$ be a nonexpansive semigroup and $\{x_n\}$ be generated by (1.4). If

$$\lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0,$$

then $\{x_n\}$ converges strongly to a member of $F(\Gamma)$.

**Proof:** For the nonexpansive semigroup $\Gamma$, condition (2) of Theorem 3.2 is trivial and so formula (3.2) holds. Since uniformly smooth Banach space $E$ has the fixed point property for nonexpansive mapping $T(t)$ (see, for example, [11]), $T(t)$ has a fixed point $x^* \in C \cap F(\Gamma)$. The rest proof is similar to the proof of Theorem 3.5 and so we omit it. This completes the proof.

**Theorem 3.7.** Let $E$ be a real Hilbert space and $K$ be a nonempty closed convex subset of $E$. Let $\Gamma := \{T(t) : t \in R^+\}$ be a strongly continuous $L$-Lipschitzian semigroup of pseudo-contractive mappings and $\{x_n\}$ be generated by (1.4). If

$$\lim_{n \to \infty} \frac{\alpha_n}{t_n} = \lim_{n \to \infty} t_n = 0,$$

then $\{x_n\}$ converges weakly to a member of $F(\Gamma)$.

**Proof:** From Theorem 3.5 and the fact that $I - T(t)$ is demiclosed at zero for each $t \in R^+$, we know that $\{x_n\}$ is bounded and so there exists subsequence $\{x_{n_j}\} \subset \{x_n\}$ which converges weakly to some fixed point $x^* \in F(\Gamma)$. Suppose there exists another subsequence $\{x_{n_k}\} \subset \{x_n\}$ which converges weakly to $y^* \in F(\Gamma)$ with $y^* \neq x^*$. Since $\lim_{n \to \infty} \|x_n - y^*\|$ exists and Hilbert space $E$ satisfies Opial's condition, it follows from the standard argument that $y^* = x^*$. Thus, $\{x_n\}$ converges weakly to a member of $F(\Gamma)$. This completes the proof.

**Remark 3.4.** Theorems 3.5 and 3.7 extend the corresponding results of Osilike [6] from the finite family of pseudo-contractive mappings to the pseudo-contractive semigroup.
