#### Abstract

In this paper, we define two types of strongly decomposable positivity, which serve as generalizations of (dual) Nakano positivity and are stronger than the decomposable positivity introduced by S. Finski. We provide the criteria for strongly decomposable positivity of type I and type II and prove that the Schur forms of a strongly decomposable positive vector bundle of type I are weakly positive, while the Schur forms of a strongly decomposable positive vector bundle of type II are positive. These answer a question of Griffiths affirmatively for strongly decomposably positive vector bundles. Consequently, we present an algebraic proof of the positivity of Schur forms for (dual) Nakano positive vector bundles, which was initially proven by S. Finski.

## 1. Introduction

Let $\left(E, h^{E}\right)$ be a Hermitian holomorphic vector bundle of rank $r$ over a complex manifold $X$ of dimension $n$. The Chern forms $c_{i}\left(E, h^{E}\right)$ of degree $2 i, 0 \leq i \leq r$ and the total Chern form $c\left(E, h^{E}\right)$ are defined by

[^0]$$
c\left(E, h^{E}\right):=\sum_{i=0}^{r} c_{i}\left(E, h^{E}\right):=\operatorname{det}\left(\operatorname{Id}_{E}+\frac{\sqrt{-1}}{2 \pi} R^{E}\right)
$$
where $R^{E} \in A^{1,1}(X, \operatorname{End}(E))$ denotes the Chern curvature of $\left(E, h^{E}\right)$. For any $k \in \mathbb{N}$ with $1 \leq k \leq n$, let $\Lambda(k, r)$ be the set of all the partitions of $k$ by non-negative integers less than or equal to $r-$ that is, any element $\lambda=\left(\lambda_{1}, \cdots, \lambda_{k}\right) \in \Lambda(k, r)$ satisfying
$$
r \geqslant \lambda_{1} \geqslant \lambda_{2} \geqslant \cdots \geqslant \lambda_{k} \geqslant 0 \text { and }|\lambda|=\sum_{i=1}^{k} \lambda_{i}=k
$$

Each partition $\lambda \in \Lambda(k, r)$ gives rise to a Schur form by

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right):=\operatorname{det}\left(c_{\lambda_{i}-i+j}\left(E, h^{E}\right)\right)_{1 \leq i, j \leq k},
$$

which is a closed real $(k, k)$-form. The Schur forms contain the Chern forms and the signed Segre forms as special examples; for example,

$$
P_{(k, 0, \cdots, 0)}\left(c\left(E, h^{E}\right)\right)=c_{k}\left(E, h^{E}\right)
$$

and

$$
P_{(1, \cdots, 1,0, \cdots, 0)}\left(c\left(E, h^{E}\right)\right)=(-1)^{k} s_{k}\left(E, h^{E}\right) .
$$

In [14, Page 129, Conjecture (0.7)], Griffiths conjectured the numerical positivity of Griffiths positive vector bundles (see (2.3) for a definition); that is, if ( $E, h^{E}$ ) is a Griffiths positive vector bundle, then

$$
\begin{equation*}
\int_{V} P\left(c_{1}, \cdots, c_{s}\right)>0 \tag{1.1}
\end{equation*}
$$

where $P\left(c_{1}, \cdots, c_{s}\right)$ is a positive polynomial in the Chern classes $c_{1}, \cdots, c_{s}$ of any quotient bundle $Q$ of $\left.E\right|_{V}, V \subset X$ is any complex analytic subvariety. Bloch-Gieseker [2] proved that all Chern classes of an ample vector bundle satisfy (1.1). Fulton-Lazarsfeld [11, Theorem I] extended Bloch-Gieseker's result and proved all Schur polynomials are numerically positive for ample vector bundles. For nef vector bundles over compact Kähler manifolds, Demailly-Peternell-Schneider [5, Theorem 2.5] proved the numerical semi-positivity of all Schur polynomials.

Griffiths [14, Page 247] also conjectured (1.1) holds on the level of the differential forms, which can be reformulated as follows; see [9, Page 1541, Question of Griffiths].

Question 1.1 (Griffiths). Let $P \in \mathbb{R}\left[c_{1}, \ldots, c_{r}\right]$ be a non-zero non-negative linear combination of Schur polynomials of weighted degree $k$. Are the forms $P\left(c_{1}\left(E, h^{E}\right), \ldots, c_{r}\left(E, h^{E}\right)\right)$ weakly positive for any Griffiths positive vector bundle ( $E, h^{E}$ ) over a complex manifold $X$ of dimension $n, n \geqslant k$ ?

Recall that a real ( $k, k$ )-form $u$ is called weakly positive (resp. non-negative) if $u \wedge(\sqrt{-1})^{(n-k)^{2}} \beta \wedge \bar{\beta}>$ 0 (resp. $\geq 0$ ) for any non-zero decomposable ( $n-k, 0$ )-form $\beta=\beta_{1} \wedge \cdots \wedge \beta_{n-k}$, where $\beta_{i}, 1 \leq i \leq n-k$ are ( 1,0 )-forms; see Definition 3.1 for the definitions of (weakly) positive (resp. non-negative) vector bundles.

Griffiths [14, Page 249] proved that the second Chern form of a Griffiths positive vector bundle is positive by using Schwarz inequality. Guler [13, Theorem 1.1] verified Question 1.1 for all signed Segre forms, and Diverio-Fagioli [6] showed the positivity of several other polynomials in the Chern forms of a Griffiths (semi)positive vector bundle by considering the pushforward of a flag bundle, including the later developments [7, 8]. See Xiao [20] and Ross-Toma [18] for other related results of ample vector bundles.

For Bott-Chern non-negative vector bundles, Bott-Chern [3, Lemma 5.3, (5.5)] proved that all Chern forms are non-negative. Li [17, Proposition 3.1] extended Bott-Chern's result and obtained all

Schur forms are non-negative. Later, Finski [9, Theorem 2.15] proved the equivalence of Bott-Chern non-negativity and dual Nakano non-negativity. Moreover, using a purely algebraic method, Finski [9, Section 3.4] proved that all Schur forms of a Nakano non-negative vector bundle are non-negative. For (dual) Nakano positive vector bundles, Finski [9, Theorem 1.1] proved that all Schur forms are positive by the refinement of the determinantal formula of Kempf-Laksov on the level of differential forms. However, as pointed out by Finski [9, Remark 3.18], the above algebraic method can be used to deal with the case of non-negativity, while for the positivity statement, it is not clear if one can refine the algebraic method because there is no similar criterion for (dual) Nakano positivity (see [9, Remark 2.16]) and there is little known about the specific structure of the forms defined in [9, (3.83)]. This motivates the author to study the question of Griffiths (Question 1.1) by developing the purely algebraic method.

In [9, Section 2.3], Finski introduced the definition of decomposably positive vector bundles (see Definition 2.2), which is a generalization of both Nakano positivity and dual Nakano positivity, and coincides with Griffiths positivity for $n \cdot r \leq 6$. So it is natural to wonder if Question 1.1 holds for such positive vector bundles. In this paper, we introduce two new notions of positivity of vector bundles, called strongly decomposable positivity of type I and type II; see Definition 2.4 and Definition 2.7. They fall in between (dual) Nakano positivity and decomposable positivity. Roughly speaking, ( $E, h^{E}$ ) is strongly decomposably positive of type I if, for any $x \in X$, there is a decomposition $T_{x}^{1,0} X=U_{x} \oplus V_{x}$ such that it is Nakano positive in the subspaces $E_{x} \otimes U_{x}$ and dual Nakano positive in the subspace $\bar{E}_{x} \otimes V_{x}$, and the cross curvature terms vanish; see Definition 2.4. Using the purely algebraic method, we answer Question 1.1 affirmatively for strongly decomposably positive vector bundles of type I.
Theorem 1.2. Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle of type I over a complex manifold $X, \operatorname{rank} E=r$, and $\operatorname{dim} X=n$. Then the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is weakly positive for any partition $\lambda \in \Lambda(k, r), k \leq n$ and $k \in \mathbb{N}$.

The proof of the theorem above primarily involves presenting an equivalent characterization of a strongly decomposably positive vector bundle of type I. While previous algebraic methods can handle the non-negative cases, for the strictly positive situations, by utilizing our equivalent characterization, we can derive a contradiction if the Schur form is not weakly positive.

From [15, Theorem 1.2], a real ( $k, k$ )-form $u$ is non-negative if and only if $u$ can be written as

$$
\begin{equation*}
u=\sum_{s=1}^{N}(\sqrt{-1})^{k^{2}} \alpha_{s} \wedge \overline{\alpha_{s}} \tag{1.2}
\end{equation*}
$$

for some ( $k, 0$ )-forms $\alpha_{s}, 1 \leq s \leq N$. By (4.15) and (4.16), the Schur form has the following form:

$$
\begin{equation*}
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{1}{2 \pi}\right)^{k}\left(\frac{1}{k!}\right)^{2}(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c, \epsilon}(-1)^{|\epsilon|+k} \psi_{\rho t c \epsilon} \wedge \overline{\psi_{\rho t c \epsilon}} \tag{1.3}
\end{equation*}
$$

where $\psi_{\rho t c \epsilon}$ is a $(|\epsilon|, k-|\epsilon|)$-form and is defined by

$$
\begin{equation*}
\psi_{\rho t c \epsilon}:=\sum_{\sigma \in S_{k}} q_{\sigma t} \bigwedge_{j=1}^{k}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}}\right)^{\epsilon_{j}} \wedge\left(\overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}} . \tag{1.4}
\end{equation*}
$$

It is not clear how to express (1.3) as in (1.2) in the general case. Hence, it seems hard to prove that the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is a positive ( $\left.k, k\right)$-form by using the algebraic method. However, if $\left(E, h^{E}\right)$ is Nakano positive or dual Nakano positive, it is equivalent to $A=0$ or $B=0$. For example, for $A=0$, (1.4) gives

$$
\psi_{\rho t c \epsilon_{1}}=\sum_{\sigma \in S_{k}} q_{\sigma t} \bigwedge_{j=1}^{k} \overline{B_{\rho_{\sigma(j)} c_{j}}}, \quad \epsilon_{1}=(1, \cdots, 1)
$$

and $\psi_{\rho t c \epsilon}=0$ for any $\epsilon \neq \epsilon_{1}$. Then the Schur form is given by

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{1}{2 \pi}\right)^{k}\left(\frac{1}{k!}\right)^{2}(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c} \psi_{\rho t c \epsilon_{1}} \wedge \overline{\psi_{\rho t c \epsilon_{1}}},
$$

which satisfies (1.2) because $\psi_{\rho t c \epsilon_{1}}$ is a $(k, 0)$-form. As a result, we can give an algebraic proof of the following positivity of Schur forms for (dual) Nakano positive vector bundles.
Theorem 1.3 (Finski [9, Theorem 1.1]). Let $\left(E, h^{E}\right)$ be a (dual) Nakano positive vector bundle of rank $r$ over a complex manifold $X$ of dimension $n$. Then for any $k \in \mathbb{N}, k \leqslant n$, and $\lambda \in \Lambda(k, r)$, the $(k, k)$-form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is positive.

Inspired by the definition of the strongly decomposable positivity of type $I$, it is natural to define the strongly decomposable positivity of type II by decomposing the vector bundle, which is the direct sum of Nakano positive and dual Nakano positive vector bundles point-wisely; see Definition 2.7. By Littlewood-Richardson rule (see [10, Chapter 5]), the Schur class of direct sum $E \oplus F$ can be given by

$$
P_{\lambda}(c(E \oplus F))=\sum_{\mu, \nu} c_{\mu \nu}^{\lambda} P_{\mu}(c(E)) P_{\nu}(c(F))
$$

where $c_{\mu \nu}^{\lambda}(\geq 0)$ is a Littlewood-Richardson coefficient. In this paper, by refining the above identity on the level of differential forms and using Theorem 1.3, we obtain the following.

Theorem 1.4. Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle of type II over a complex manifold $X, \operatorname{rank} E=r$, and $\operatorname{dim} X=n$. Then the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is positive for any partition $\lambda \in \Lambda(k, r), k \leq n$ and $k \in \mathbb{N}$.

Remark 1.5. Comparing Theorem 1.2 with Theorem 1.4, it is natural to ask if the Schur forms are positive for a strongly decomposably vector bundle of type I.

The article is organized as follows. In Section 2, we define two types of strongly decomposably positive vector bundles, which are the generalizations of both Nakano positivity and dual Nakano positivity, and are stronger than decomposable positivity. In Section 3, we recall the positivity notions for differential forms and show the positivity of the product of two positive forms. In Section 4, we give a criterion of a strongly decomposably positive vector bundle of type I, recall the definitions of Schur forms and Griffiths cone, and then prove the weak positivity of Schur forms, Theorem 1.2 and Theorem 1.3 are established in this section. In Section 5, we give a criterion of a strongly decomposably positive vector bundle of type II and prove the positivity of Schur forms. Theorem 1.4 is established in this section.

## 2. Strongly decomposably positive vector bundles

This section defines two types of strongly decomposably positive vector bundles.

### 2.1. Connections and curvatures

In this subsection, we recall the definitions of the Chern connection and its curvature for a Hermitian holomorphic vector bundle. One can refer to [16, Chapter 1] for more details. We use the Einstein summation convention in this paper.

Let $\pi:\left(E, h^{E}\right) \rightarrow X$ be a Hermitian holomorphic vector bundle over a complex manifold $X$, $\operatorname{rank} E=r$ and $\operatorname{dim} X=n$. Let $\nabla^{E}$ be the Chern connection of $\left(E, h^{E}\right)$, which preserves the metric $h^{E}$ and is of $(1,0)$-type. With respect to a local holomorphic frame $\left\{e_{i}\right\}_{1 \leq i \leq r}$ of $E$, one has

$$
\begin{equation*}
\nabla^{E} e_{i}=\theta_{i}^{j} e_{j} \tag{2.1}
\end{equation*}
$$

where $\theta=\left(\theta_{i}^{j}\right)\left(j\right.$ row, $i$ column) is the connection form of $\nabla^{E}$. More precisely,

$$
\theta_{i}^{j}=\partial h_{i \bar{k}} h^{\bar{k} j}
$$

where $h_{i \bar{k}}:=h\left(e_{i}, e_{k}\right)$. In terms of matrix form, it is

$$
\theta^{\top}=\partial h \cdot h^{-1} .
$$

Considering $e=\left(e_{1}, \cdots, e_{r}\right)$ as a row vector, then (2.1) can be written as

$$
\nabla^{E} e=e \cdot \theta
$$

Let $R^{E}=\left(\nabla^{E}\right)^{2} \in A^{1,1}(X, \operatorname{End}(E))$ denote the Chern curvature of $\left(E, h^{E}\right)$, and write

$$
R^{E}=R_{i}^{j} e_{j} \otimes e^{i} \in A^{1,1}(X, \operatorname{End}(E)),
$$

where $R=\left(R_{i}^{j}\right)\left(j\right.$ row, $i$ column) is the curvature matrix whose entries are ( 1,1 )-forms and $\left\{e^{i}\right\}_{1 \leq i \leq r}$ denotes the dual frame of $\left\{e_{i}\right\}_{1 \leq i \leq r}$. The curvature matrix $R=\left(R_{i}^{j}\right)$ is given by

$$
R_{i}^{j}=d \theta_{i}^{j}+\theta_{k}^{j} \wedge \theta_{i}^{k}=\bar{\partial} \theta_{i}^{j}
$$

If $\left\{\tilde{e}_{i}\right\}_{1 \leq i \leq r}$ is another local holomorphic frame of $E$ with $\tilde{e}_{i}=a_{i}^{j} e_{j}$, then

$$
\tilde{e}=e \cdot a \text {, }
$$

where $\tilde{e}:=\left(\tilde{e}_{1}, \cdots, \tilde{e}_{r}\right)$ and $a=\left(a_{j}^{i}\right)$. Denote by $\widetilde{R}$ the curvature matrix with respect to the local frame $\left\{\tilde{e}_{i}\right\}_{1 \leq i \leq r}$. Then

$$
\begin{equation*}
\widetilde{R}=a^{-1} \cdot R \cdot a \tag{2.2}
\end{equation*}
$$

Let $\left\{z^{\alpha}\right\}_{1 \leq \alpha \leq n}$ be local holomorphic coordinates of $X$. Write

$$
R_{i}^{j}=R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}
$$

and denote

$$
R_{i \bar{j}}:=R_{i}^{k} h_{k \bar{j}}=R_{i \bar{j} \alpha \bar{\beta}} d z^{\alpha} \wedge d \bar{z}^{\beta}
$$

so that

$$
R_{i \bar{j} \alpha \bar{\beta}}=R_{i \alpha \bar{\beta}}^{k} h_{k \bar{j}}=-\partial_{\alpha} \partial_{\bar{\beta}} h_{i \bar{j}}+h^{\bar{l} k} \partial_{\alpha} h_{i \bar{l}} \partial_{\bar{\beta}} h_{k \bar{j}},
$$

where $\partial_{\alpha}:=\partial / \partial z^{\alpha}$ and $\partial_{\bar{\beta}}:=\partial / \partial \bar{z}^{\beta}$.

### 2.2. Strongly decomposable positivity

This subsection defines two types of strongly decomposably positive vector bundles. Firstly, we recall the following definitions of Nakano positive and dual Nakano positive vector bundles.

Definition 2.1 ((Dual) Nakano positive). A Hermitian holomorphic vector bundle ( $E, h^{E}$ ) is called Nakano positive (resp. non-negative) if

$$
R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}>0(\text { resp. } \geq 0)
$$

for any non-zero element $u=u^{i \alpha} e_{i} \otimes \partial_{\alpha} \in E \otimes T^{1,0} X .\left(E, h^{E}\right)$ is called dual Nakano positive (nonnegative) if

$$
R_{i \bar{j} \alpha \bar{\beta}} v^{\bar{j} \alpha} \overline{v^{\bar{i} \beta}}>0(\text { resp. } \geq 0)
$$

for any non-zero element $v=v^{\bar{j} \alpha} \bar{e}_{j} \otimes \partial_{\alpha} \in \bar{E} \otimes T^{1,0} X$.
In [9, Definition 2.18], S. Finski introduced the following new notion of positivity for vector bundles: decomposable positivity.
Definition 2.2 (Decomposably positive). A Hermitian vector bundle $\left(E, h^{E}\right)$ is called decomposably non-negative if for any $x \in X$, there is a number $N \in \mathbb{N}$ and linear (respectively sesquilinear) forms $l_{p}^{\prime}: T_{x}^{1,0} X \otimes E_{x} \rightarrow \mathbb{C}$ (respectively $l_{p}: T_{x}^{1,0} X \otimes E_{x} \rightarrow \mathbb{C}$ ), $p=1, \ldots, N$, such that for any $v \in T_{x}^{1,0} X, \xi \in E_{x}$, we have

$$
\frac{1}{2 \pi}\left\langle R_{x}^{E}(v, \bar{v}) \xi, \xi\right\rangle_{h^{E}}=\sum_{p=1}^{N}\left|l_{p}(v, \xi)\right|^{2}+\sum_{p=1}^{N}\left|l_{p}^{\prime}(v, \xi)\right|^{2}
$$

We say that it is decomposably positive if, moreover, $\left\langle R_{x}^{E}(v, \bar{v}) \xi, \xi\right\rangle_{h^{E}} \neq 0$ for $v, \xi \neq 0$.
Remark 2.3. From the above definition, a (dual) Nakano positive vector bundle must be decomposably positive. From [9, Proposition 2.21], for $n \cdot r \leq 6$ decomposable positivity is equivalent to Griffiths positivity; that is,

$$
\begin{equation*}
R_{i \bar{j} \alpha \bar{\beta}} v^{i} \bar{v}^{j} \xi^{\alpha} \bar{\xi}^{\beta}>0 \tag{2.3}
\end{equation*}
$$

for any non-zero $\xi=\xi^{\alpha} \partial_{\alpha} \in T^{1,0} X$ and $v=v^{i} e_{i} \in E$. Decomposable positivity is strictly stronger than Griffiths positivity for all other $n, r \neq 1$.

Next, we introduce the notion of strongly decomposable positivity, which falls in between (dual) Nakano positivity and decomposable positivity.
Definition 2.4 (Strongly decomposably positive of type I). A Hermitian vector bundle ( $E, h^{E}$ ) is called a strongly decomposably positive (resp. non-negative) vector bundle of type I if, for any $x \in X$, there exists a decomposition $T_{x}^{1,0} X=U_{x} \oplus V_{x}$ such that

$$
R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}>0(\text { resp. } \geq 0), R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{v^{\prime} j \beta}=0, R_{i \bar{j} \alpha \bar{\beta}} v^{\bar{j} \alpha} \overline{v^{\overline{i \beta}}}>0(\text { resp. } \geq 0)
$$

for any non-zero elements $u=u^{i \alpha} e_{i} \otimes \partial_{\alpha} \in E_{x} \otimes U_{x}, v^{\prime}=v^{\prime} j \beta e_{j} \otimes \partial_{\beta} \in E_{x} \otimes V_{x}$ and $v=v^{\bar{j} \alpha} \bar{e}_{j} \otimes \partial_{\alpha} \in$ $\bar{E}_{x} \otimes V_{x}$.
Remark 2.5. In fact, by taking $u^{i \alpha}=1=v^{\prime} j \beta$ in the above definition, the condition $R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{v^{\prime} j \beta}=0$ is equivalent to $R_{i \bar{j} \alpha \bar{\beta}}=0$ for any $\partial_{\alpha} \in U_{x}$ and $\partial_{\beta} \in V_{x}$ (i.e., $R\left(U_{x}, \overline{V_{x}}\right)=0$ ), which is also equivalent to $R_{i \bar{j} \alpha \bar{\beta}} \nu^{\bar{j}} \overline{u^{\prime} \bar{i} \beta}=0$ for any $v=v^{\bar{j} \alpha} \bar{e}_{j} \otimes \partial_{\alpha} \in \bar{E}_{x} \otimes V_{x}$ and $u^{\prime}=u^{\prime} \bar{i} \beta \bar{e}_{i} \otimes \partial_{\beta} \in \bar{E}_{x} \otimes U_{x}$. Hence, the above definition is invariant under switching $U$ and $V$.

For any point $x \in X$, if $V_{x}=\{0\}$ (resp. $U_{x}=\{0\}$ ), then strongly decomposable positivity of type I is exactly Nakano positive (resp. dual Nakano positive).
Example 2.6. Let $\pi_{1}:\left(E_{1}, h^{E_{1}}\right) \rightarrow X_{1}$ be a Nakano positive vector bundle and $\pi_{2}:\left(E_{2}, h^{E_{2}}\right) \rightarrow X_{2}$ be a dual Nakano positive vector bundle. Denote by $p_{i}: X_{1} \times X_{2} \rightarrow X_{i}, i=1$, 2, the natural projections. Then

$$
\pi_{\oplus}:\left(p_{1}^{*} E_{1} \oplus p_{2}^{*} E_{2}, p_{1}^{*} h^{E_{1}} \oplus p_{2}^{*} h^{E_{2}}\right) \rightarrow X_{1} \times X_{2}
$$

is a strongly decomposably non-negative vector bundle of type I, and

$$
\pi_{\otimes}:\left(p_{1}^{*} E_{1} \otimes p_{2}^{*} E_{2}, p_{1}^{*} h^{E_{1}} \otimes p_{2}^{*} h^{E_{2}}\right) \rightarrow X_{1} \times X_{2}
$$

is a strongly decomposably positive vector bundle of type I.
From Definition 2.4, a strongly decomposably positive vector bundle ( $E, h^{E}$ ) of type I means that there is a decomposition of holomorphic tangent bundle $T_{x}^{1,0} X=U_{x} \oplus V_{x}$, such that ( $E, h^{E}$ ) is Nakano positive in $E_{x} \otimes U_{x}$ and dual Nakano positive in $\bar{E}_{x} \otimes V_{x}$, and the cross curvature terms vanish. Naturally, one may define another strongly decomposable positivity of vector bundles by decomposing the vector bundle.

Definition 2.7 (Strongly decomposably positive of type II). We call ( $E, h^{E}$ ) a strongly decomposably positive (resp. non-negative) vector bundle of type II if, for any $x \in X$, there is an orthogonal decomposition of $\left(E_{x},\left.h^{E}\right|_{E_{x}}\right), E_{x}=E_{1, x} \oplus E_{2, x}$, such that the Chern curvature $R_{x}^{E}$ has the form

$$
R_{x}^{E}=\left(\begin{array}{cc}
\left.R_{x}^{E}\right|_{E_{1, x}} & 0 \\
0 & \left.R_{x}^{E}\right|_{E_{2, x}}
\end{array}\right)
$$

and $R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}>0$ (resp. $\geq 0$ ) for any non-zero $u=u^{i \alpha} e_{i} \otimes \partial_{\alpha} \in E_{1, x} \otimes T_{x}^{1,0} X, R_{i \bar{j} \alpha \bar{\beta}} i^{i \bar{\beta} \overline{v^{j} \bar{\alpha}}}>0$ (resp. $\geq 0$ ) for any non-zero $v=v^{i \bar{\beta}} e_{i} \otimes \partial_{\bar{\beta}} \in E_{2, x} \otimes T_{x}^{0,1} X$.

A simple example of a strongly decomposably vector bundle of type II is as follows.
Example 2.8. Let $\left(E, h^{E}\right)$ be a Nakano positive vector bundle and ( $F, h^{F}$ ) be a dual Nakano positive vector bundle over a complex manifold $X$. Then $\left(E \oplus F, h^{E} \oplus h^{F}\right)$ is a strongly decomposably positive vector bundle of type II.

By Definition 2.4 and Definition 2.7, a strongly decomposably positive vector bundle is defined as follows.

Definition 2.9 (Strongly decomposably positive). A Hermitian vector bundle ( $E, h^{E}$ ) is called strongly decomposably positive if it is a strongly decomposably positive vector bundle of type I or type II.

Similarly, one can define strongly decomposably negative (non-positive) vector bundles. Note that the dual of the Nakano positive (negative) vector bundle is dual Nakano negative (positive), so we have the following.

Proposition 2.10. A Hermitian vector bundle $\left(E, h^{E}\right)$ is a strongly decomposably positive (nonnegative) vector bundle of type I (type II) if and only if $\left(E^{*}, h^{E^{*}}\right)$ is a strongly decomposably negative (non-positive) vector bundle of type I (type II).

Remark 2.11. Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle and $Q$ be a quotient bundle of $E$. The curvature of the bundle $Q$ is given by

$$
R^{Q}=\left.R^{E}\right|_{Q}+C \wedge \bar{C}^{\top}
$$

for some matrix $C$ whose entries are (1,0)-forms. From the criteria of strongly decomposably positive vector bundles, Theorem 4.3 and Theorem 5.2, and the above curvature formula of quotient bundles, the quotient bundle $\left(Q, h^{Q}\right)$ ceases to be a strongly decomposably positive vector bundle in general.

### 2.3. Relation to decomposable positivity

From the equivalent descriptions of Nakano non-negative and dual non-negative due to S . Finski [9, Theorem 2.15 and 2.17], one has the following:

Proposition 2.12. A Hermitian vector bundle $\left(E, h^{E}\right)$ is decomposably non-negative if and only if the Chern curvature matrix has the form

$$
\begin{equation*}
R=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top} \tag{2.4}
\end{equation*}
$$

with respect to a unitary frame, where $A$ (resp. $B$ ) is a $r \times N$ matrix with ( 1,0 )-forms (resp. ( 0,1 )-forms) as entries.

Proof. From Definition 2.2, $\left(E, h^{E}\right)$ is decomposably positive if for any $x \in X$, there is a number $N \in \mathbb{N}$ and linear (respectively sesquilinear) forms $l_{p}^{\prime}: T_{x}^{1,0} X \otimes E_{x} \rightarrow \mathbb{C}$ (respectively $l_{p}: T_{x}^{1,0} X \otimes E_{x} \rightarrow \mathbb{C}$ ), $p=1, \ldots, N$, such that for any $v \in T_{x}^{1,0} X, \xi \in E_{x}$, we have

$$
\begin{equation*}
\left\langle R_{x}^{E}(v, \bar{v}) \xi, \xi\right\rangle_{h^{E}}=\sum_{p=1}^{N}\left|l_{p}(v, \xi)\right|^{2}+\sum_{p=1}^{N}\left|l_{p}^{\prime}(v, \xi)\right|^{2} \tag{2.5}
\end{equation*}
$$

We denote

$$
l_{p}(v, \xi)=l_{i p \bar{\beta}} v^{i} \bar{\xi}^{\beta}, \quad l_{p}^{\prime}(v, \xi)=l_{i p \alpha}^{\prime} v^{i} \xi^{\alpha}
$$

and set $A=\left(A_{j p}\right)$ and $B=\left(B_{j p}\right)$ by

$$
A_{j p}:=A_{j p \alpha} d z^{\alpha}=\overline{l_{j p \bar{\alpha}}} d z^{\alpha}, \quad B_{j p}:=B_{j p \bar{\beta}} d \bar{z}^{\beta}=\overline{l_{j p \beta}^{\prime}} d \bar{z}^{\beta} .
$$

Then (2.5) is equivalent to

$$
\begin{align*}
R_{i \bar{j} \alpha \bar{\beta}} & =\sum_{p=1}^{N} l_{i p \bar{\beta}} \overline{l_{j p \bar{\alpha}}}+\sum_{p=1}^{N} l_{i p \alpha}^{\prime} \overline{l_{j p \beta}^{\prime}} \\
& =\sum_{p=1}^{N} A_{j p \alpha} \overline{A_{i p \beta}}+\sum_{i=1}^{N} B_{j p \bar{\beta}} \overline{B_{i p \bar{\alpha}}} . \tag{2.6}
\end{align*}
$$

With respect to a unitary frame, $R_{i \alpha \bar{\beta}}^{j}=R_{i \bar{j} \alpha \bar{\beta}}$ and (2.6) is equivalent to

$$
R=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top}
$$

which completes the proof.
From Proposition 2.12 and Definition 2.2, ( $E, h^{E}$ ) is decomposably positive if and only if (2.4) holds and $\left\langle R_{x}^{E}(v, \bar{v}) \xi, \xi\right\rangle_{h^{E}} \neq 0$ for $v, \xi \neq 0$. By Theorem 4.3 and Theorem 5.2, we have the following:

Corollary 2.13. If $\left(E, h^{E}\right)$ is a strongly decomposably positive vector bundle of type I or type II, then $\left(E, h^{E}\right)$ is decomposably positive.

However, from Theorem 4.3 and Theorem 5.2, the two types of strongly decomposably positive vector bundles cannot contain each other. Both are the generalizations of (dual) Nakano positive vector bundles and are stronger than decomposable positivity. One can refer to the following Figure 1.

Remark 2.14. Note that the set of curvature operators of a vector bundle, whether they are Griffiths positive, decomposably positive or (dual) Nakano positive, is closed under addition. Specifically, if both $R_{1}$ and $R_{2}$ are curvature operators that fall into any of these categories, then their sum $R_{1}+R_{2}$ will also belong to the same category. Moreover, a decomposably positive curvature operator can be expressed as the sum of a Nakano positive curvature operator and a dual Nakano positive curvature operator. As a result, it is also the sum of the strongly decomposable positivity of type I (or type II). Since the strongly

Figure 1. Relations of several notions of positivity.
decomposable positivity of type I (type II) is strictly stronger than decomposable positivity, the set of strongly decomposable positive curvature operators of type I (or type II) is not closed under addition.

## 3. Positivity notions for differential forms

In this section, we recall positivity notions for differential forms. For more details, one can refer to [7, Section 1.1] and [15, 9].

Let $V$ be a complex vector space of dimension $n$ and let $\left(e_{1}, \cdots, e_{n}\right)$ be a basis of $V$. Denote by $\left(e^{1}, \cdots, e^{n}\right)$ the dual basis of $V^{*}$. Let $\Lambda^{p, q} V^{*}$ denote the space of $(p, q)$-forms and $\Lambda_{\mathbb{R}}^{p, p} V^{*} \subset \Lambda^{p, p} V^{*}$ be the subspace of real ( $p, p$ )-forms.

Definition 3.1. A form $v \in \Lambda^{n, n} V^{*}$ is called a non-negative (resp. positive) volume form if $v=\tau \sqrt{-1} e^{1} \wedge \bar{e}^{1} \wedge \cdots \wedge \sqrt{-1} e^{n} \wedge \bar{e}^{n}$ for some $\tau \in \mathbb{R}, \tau \geq 0$ (resp. $\tau>0$ ).

Now we set $q=n-p$. A $(q, 0)$-form $\beta$ is called decomposable if $\beta=\beta_{1} \wedge \cdots \wedge \beta_{q}$ for some $\beta_{1}, \ldots, \beta_{q} \in V^{*}$.

Definition 3.2. A real $(p, p)$-form $u \in \Lambda_{\mathbb{R}}^{p, p} V^{*}$ is called

- weakly non-negative (resp. weakly positive) if for every non-zero $\beta \in \Lambda^{q, 0} V^{*}$ decomposable, $u \wedge(\sqrt{-1})^{q^{2}} \beta \wedge \bar{\beta}$ is a non-negative (resp. positive) volume form;
- non-negative (resp. positive) if for every non-zero $\beta \in \Lambda^{q, 0} V^{*}, u \wedge(\sqrt{-1})^{q^{2}} \beta \wedge \bar{\beta}$ is a non-negative (resp. positive) volume form;
- strongly non-negative (resp. strongly positive) if there are decomposable forms $\alpha_{1}, \ldots, \alpha_{N} \in \Lambda^{p, 0} V^{*}$ such that $u=\sum_{s=1}^{N}(\sqrt{-1})^{p^{2}} \alpha_{s} \wedge \overline{\alpha_{s}}$.

Remark 3.3. Let $\mathrm{WP}^{p} V^{*}, \mathrm{P}^{p} V^{*}$ and $\mathrm{SP}^{p} V^{*}$ denote respectively the closed positive convex cones contained in $\Lambda_{\mathbb{R}}^{p, p} V^{\vee}$ spanned by weakly non-negative, non-negative and strongly non-negative forms. Then

$$
\begin{equation*}
\mathrm{SP}^{p} V^{*} \subseteq \mathrm{P}^{p} V^{*} \subseteq \mathrm{WP}^{p} V^{*} \tag{3.1}
\end{equation*}
$$

Note that the above two inclusions become equalities for $p=0,1, n-1, n$, and the inclusions are strict for $2 \leq p \leq n-2$; see, for example, [7, Remark 1.7, 1.8] and [15].

Proposition 3.4. If $u$ is a positive $(k, k)$-form and $v$ is a positive $(l, l)$-form, $k+l \leq n$, then $u \wedge v$ is a positive $(k+l, k+l)$-form.

Proof. By [15, Corollary 1.3 (a)], $u \wedge v$ is a non-negative $(k+l, k+l)$-form; that is, for any non-zero $\beta \in \Lambda^{n-k-l, 0} V^{*}$,

$$
\begin{equation*}
u \wedge v \wedge(\sqrt{-1})^{(n-k-l)^{2}} \beta \wedge \bar{\beta} \geq 0 \tag{3.2}
\end{equation*}
$$

By [15, Theorem 1.2], $v$ has the form

$$
v=\sum_{s=1}^{N}(\sqrt{-1})^{l^{2}} \alpha_{s} \wedge \overline{\alpha_{s}}
$$

for some ( $l, 0$ )-forms $\alpha_{s}, 1 \leq s \leq N$. So

$$
\begin{aligned}
u \wedge v \wedge(\sqrt{-1})^{(n-k-l)^{2}} \beta \wedge \bar{\beta} & =\sum_{s=1}^{N} u \wedge(\sqrt{-1})^{l^{2}} \alpha_{s} \wedge \overline{\alpha_{s}} \wedge(\sqrt{-1})^{(n-k-l)^{2}} \beta \wedge \bar{\beta} \\
& =\sum_{s=1}^{N} u \wedge(\sqrt{-1})^{(n-k)^{2}} \alpha_{s} \wedge \beta \wedge \overline{\alpha_{s} \wedge \beta}
\end{aligned}
$$

Thus, the equality in (3.2) holds if and only if

$$
u \wedge(\sqrt{-1})^{(n-k)^{2}} \alpha_{s} \wedge \beta \wedge \overline{\alpha_{s} \wedge \beta}=0, \quad 1 \leq s \leq N
$$

which is equivalent to

$$
\alpha_{s} \wedge \beta=0, \quad 1 \leq s \leq N
$$

Thus,

$$
v \wedge(\sqrt{-1})^{(n-k-l)^{2}} \beta \wedge \bar{\beta}=\sum_{s=1}^{N}(\sqrt{-1})^{(n-k)^{2}} \alpha_{s} \wedge \beta \wedge \overline{\alpha_{s} \wedge \beta}=0,
$$

which contradicts the positivity of $v$. Hence,

$$
u \wedge v \wedge(\sqrt{-1})^{(n-k-l)^{2}} \beta \wedge \bar{\beta}>0
$$

for any non-zero $\beta \in \Lambda^{n-k-l, 0} V^{*}$ (i.e., $u \wedge v$ is positive).
Let $X$ be a complex manifold of dimension $n$ and denote by $A^{p, q}(X)$ the space of all smooth $(p, q)$ forms.

Definition 3.5. A real ( $p, p$ )-form $\alpha \in A^{p, p}(X)$ is called weakly non-negative (weakly positive), nonnegative (positive) or strongly non-negative (strongly positive) if for any $x \in X, \alpha_{x} \in \Lambda_{\mathbb{R}}^{p, p}\left(T_{x}^{1,0} X\right)^{*}$ is weakly non-negative (weakly positive), non-negative (positive) or strongly non-negative (strongly positive), respectively.

## 4. Strongly decomposable positivity of type I

In this section, we give a criterion of strongly decomposably positive vector bundles of type I and prove the weak positivity of Schur forms.

### 4.1. A criterion of type I positivity

In this subsection, following S. Finski's approach [9, Theorem 2.15, 2.17], we give a criterion for the strongly decomposable positivity (non-negativity) of type I by using M.-D. Choi's results.

Let $\left(E, h^{E}\right)$ be a strongly decomposably non-negative vector bundle of type I . For any $x \in X$, there exists a decomposition $T_{x}^{1,0} X=U_{x} \oplus V_{x}$. One can take local holomorphic coordinates $\left\{z^{1}, \cdots, z^{n}\right\}$ around $x$ such that

$$
U_{x}=\operatorname{span}_{\mathbb{C}}\left\{\partial_{1}, \cdots, \partial_{n_{0}}\right\}, V_{x}=\operatorname{span}_{\mathbb{C}}\left\{\partial_{n_{0}+1}, \cdots, \partial_{n}\right\},
$$

where $n_{0}:=\operatorname{dim} U_{x}$ and recall that $\partial_{\alpha}:=\partial / \partial z^{\alpha}$. Let $\left\{e_{i}\right\}_{1 \leq i \leq r}$ be a local holomorphic frame of $E$ such that

$$
h_{i \bar{j}}(x)=h^{E}\left(e_{i}(x), e_{j}(x)\right)=\delta_{i j} .
$$

With respect to $\left\{z^{\alpha}\right\}_{1 \leq \alpha \leq n}$ and $\left\{e_{i}\right\}_{1 \leq i \leq r}$, the Chern curvature matrix $R=\left(R_{i}^{j}\right)$ at $x \in X$ has the following expression:

$$
\begin{align*}
R_{i}^{j}= & R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta} \\
= & \sum_{\alpha, \beta=1}^{n_{0}} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}+\sum_{\alpha, \beta=n_{0}+1}^{n} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}  \tag{4.1}\\
& +\sum_{\alpha=1}^{n_{0}} \sum_{\beta=n_{0}+1}^{n} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}+\sum_{\alpha=n_{0}+1}^{n} \sum_{\beta=1}^{n_{0}} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta} .
\end{align*}
$$

By assumption, $\left(E, h^{E}\right)$ is strongly decomposably non-negative of type I , so

$$
\sum_{\alpha=1}^{n_{0}} \sum_{\beta=n_{0}+1}^{n} R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{v^{\prime} j \beta}=0
$$

for any $\sum_{\alpha=1}^{n_{0}} u^{i \alpha} e_{i} \otimes \partial_{\alpha}$ and $\sum_{\beta=n_{0}+1}^{n} v^{\prime} j \beta e_{j} \otimes \partial_{\beta}$, which follows that

$$
\begin{equation*}
R_{i \bar{j} \alpha \bar{\beta}}=0, \quad 1 \leq \alpha \leq n_{0}, n_{0}+1 \leq \beta \leq n . \tag{4.2}
\end{equation*}
$$

By conjugation, one gets

$$
\begin{equation*}
R_{i \bar{j} \alpha \bar{\beta}}=\overline{R_{j \bar{i} \bar{\beta} \bar{\alpha}}}=0, \quad n_{0}+1 \leq \alpha \leq n, 1 \leq \beta \leq n_{0} . \tag{4.3}
\end{equation*}
$$

Substituting (4.2), (4.3) into (4.1), one has

$$
R_{i}^{j}=\sum_{\alpha, \beta=1}^{n_{0}} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}+\sum_{\alpha, \beta=n_{0}+1}^{n} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}
$$

For the local frame $\left\{\partial_{\alpha}\right\}_{1 \leq \alpha \leq n}$, we define a local metric $g$ around $x$ by

$$
g_{\alpha \bar{\beta}}=g\left(\partial_{\alpha}, \partial_{\beta}\right):=\delta_{\alpha \beta}
$$

Now we define a linear map

$$
H_{x}^{V}: \operatorname{End}\left(V_{x}\right) \rightarrow \operatorname{End}\left(E_{x}\right)
$$

by

$$
\begin{equation*}
H_{x}^{V}\left(\partial_{\alpha} \otimes d z^{\gamma}\right)=R_{i \alpha \bar{\beta}}^{j} g^{\bar{\beta} \gamma} e_{j} \otimes e^{i}=R_{i \alpha \bar{\gamma}}^{j} e_{j} \otimes e^{i} \tag{4.4}
\end{equation*}
$$

for any $n_{0}+1 \leq \alpha, \gamma \leq n$. With respect to the basis $\left\{\partial_{\alpha}\right\}_{n_{0}+1 \leq \alpha \leq n}$, the matrix of $\partial_{\alpha} \otimes d z^{\gamma} \in \operatorname{End}\left(U_{x}\right)$ is $E_{\alpha \gamma}$, which is the $\left(n-n_{0}\right) \times\left(n-n_{0}\right)$ matrix with 1 at the $(\alpha, \gamma)$-component and zeros elsewhere. The matrix of $R_{i \alpha \bar{\gamma}}^{j} e_{j} \otimes e^{i} \in \operatorname{End}\left(E_{x}\right)$ is given by $\left(R_{i \alpha \bar{\gamma}}^{j}\right)_{1 \leq j, i \leq r}(j$ row, $i$ column). In terms of matrices, (4.4) becomes

$$
\begin{equation*}
H_{x}^{V}\left(E_{\alpha \gamma}\right)=\left(R_{i \alpha \bar{\gamma}}^{j}\right)_{1 \leq j, i \leq r}=\left(R_{i \bar{j} \alpha \bar{\gamma}}\right)_{1 \leq j, i \leq r} \tag{4.5}
\end{equation*}
$$

Then $\left(H_{x}^{V}\left(E_{\alpha \gamma}\right)\right)_{n_{0}+1 \leq \alpha, \gamma \leq n}$ is a $\left(n-n_{0}\right) \times\left(n-n_{0}\right)$ block matrix with $r \times r$ matrices as entries, and

$$
\left(H_{x}^{V}\left(E_{\alpha \gamma}\right)\right)_{n_{0}+1 \leq \alpha, \gamma \leq n}=\left(\left(R_{i \bar{j} \alpha \bar{\gamma}}\right)_{1 \leq j, i \leq r}\right)_{n_{0}+1 \leq \alpha, \gamma \leq n} \quad(j \alpha \text { row, } i \gamma \text { column })
$$

Since $\left(E, h^{E}\right)$ is strongly decomposably non-negative of type I, then

$$
R_{i \bar{j} \alpha \bar{\beta}} \nu^{\bar{j} \alpha} \overline{v^{\bar{i} \beta}} \geq 0
$$

for any non-zero $v=v^{\bar{j} \alpha} e_{i} \otimes \partial_{\alpha} \in E_{x} \otimes V_{x}$, which follows that the matrix

$$
\left(H_{x}^{V}\left(E_{\alpha \gamma}\right)\right)_{n_{0}+1 \leq \alpha, \gamma \leq n}
$$

is positive semi-definite. By using [4, Theorem 2 and Theorem 1], there exist $\left(n-n_{0}\right) \times r$ matrices $V_{p}, 1 \leq p \leq N_{1}$ (one can choose $N_{1}=\left(n-n_{0}\right) \cdot r$ ) such that

$$
H_{x}^{V}\left(E_{\alpha \gamma}\right)=\sum_{p=1}^{N_{1}}{\overline{V_{p}}}^{\top} \cdot E_{\alpha \gamma} \cdot V_{p}
$$

for any $n_{0}+1 \leq \alpha, \gamma \leq n$. Combining with (4.5) and considering the ( $j, i$ ) entry, one has

$$
R_{i \alpha \bar{\beta}}^{j}=\sum_{p=1}^{N_{1}}\left({\overline{V_{p}}}^{\top} \cdot E_{\alpha \beta} \cdot V_{p}\right)_{j, i}=\sum_{p=1}^{N_{1}} \overline{\left(V_{p}\right)_{\alpha j}}\left(V_{p}\right)_{\beta i} .
$$

Hence,

$$
\begin{aligned}
\sum_{\alpha, \beta=n_{0}+1}^{n} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta} & =\sum_{\alpha, \beta=n_{0}+1}^{n} \sum_{p=1}^{N_{1}} \overline{\left(V_{p}\right)_{\alpha j}}\left(V_{p}\right)_{\beta i} d z^{\alpha} \wedge d \bar{z}^{\beta} \\
& =\sum_{p=1}^{N_{1}} A_{j p} \wedge \overline{A_{i p}}
\end{aligned}
$$

where $A_{j p}:=\sum_{\alpha=n_{0}+1}^{n} \overline{\left(V_{p}\right)_{\alpha j}} d z^{\alpha}$, and one has

$$
\left(\sum_{\alpha, \beta=n_{0}+1}^{n} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}\right)_{1 \leq j, i \leq r}=A \wedge \bar{A}^{\top},
$$

where $A=\left(A_{j p}\right)$ is a $r \times N_{1}$ matrix with (1,0)-forms in $V_{x}^{*}$ as entries.
Similarly, by considering the linear map

$$
H_{x}^{U}: \operatorname{End}\left(U_{x}\right) \rightarrow \operatorname{End}\left(E_{x}^{*}\right), \quad H_{x}^{V}\left(\partial_{\alpha} \otimes d z^{\gamma}\right)=R_{i \alpha \bar{\gamma}}^{j} e^{i} \otimes e_{j}
$$

One can obtain that

$$
\left(H_{x}^{V}\left(E_{\alpha \gamma}\right)\right)_{1 \leq \alpha, \gamma \leq n_{0}}=\left(\left(R_{i \bar{j} \alpha \bar{\gamma}}\right)_{1 \leq j, i \leq r}\right)_{1 \leq \alpha, \gamma \leq n_{0}} \quad(i \alpha \text { row, } j \gamma \text { column }),
$$

which follows that

$$
\left(\sum_{\alpha, \beta=1}^{n_{0}} R_{i \alpha \bar{\beta}}^{j} d z^{\alpha} \wedge d \bar{z}^{\beta}\right)_{1 \leq j, i \leq r}=-B \wedge \bar{B}^{\top}
$$

where $B=\left(B_{j p}\right)$ is a $r \times N_{2}$ (one can choose $N_{2}=n_{0} \cdot r$ ) matrix with ( 0,1 )-forms in $\overline{U_{x}^{*}}$ as entries.
Thus, if ( $E, h^{E}$ ) is strongly decomposably non-negative of type I , then for any $x \in X$, the Chern curvature matrix at this point has the form

$$
\begin{equation*}
R=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top} \tag{4.6}
\end{equation*}
$$

with respect to a unitary frame, where $B$ is a $r \times N_{2}$ matrix with ( 0,1 )-forms as entries, $A$ is a $r \times N_{1}$ matrix with $(1,0)$-forms as entries, and

$$
\begin{equation*}
\operatorname{span}_{\mathbb{C}}\{\bar{B}\} \cap \operatorname{span}_{\mathbb{C}}\{A\}=\{0\} \tag{4.7}
\end{equation*}
$$

where

$$
\{\bar{B}\}:=\left\{\overline{B_{i p}}, 1 \leq i \leq r, 1 \leq p \leq N_{2}\right\}
$$

and

$$
\{A\}:=\left\{A_{i p}, 1 \leq i \leq r, 1 \leq p \leq N_{1}\right\} .
$$

Remark 4.1. It is noted that the above argument is independent of the choice of unitary frames. If $\tilde{e}=e \cdot a$ is also a unitary frame, then $a$ is a unitary matrix. By (2.2), one has

$$
\begin{aligned}
\widetilde{R} & =a^{-1} \cdot\left(-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top}\right) \cdot a \\
& =-a^{-1} B \wedge{\overline{a^{-1} B}}^{\top}+a^{-1} A \wedge{\overline{a^{-1} A}}^{\top}
\end{aligned}
$$

which has the form (4.6). Moreover, $\operatorname{span}_{\mathbb{C}}\{\bar{B}\}=\operatorname{span}_{\mathbb{C}}\left\{\overline{a^{-1} B}\right\}$ and $\operatorname{span}_{\mathbb{C}}\{A\}=\operatorname{span}_{\mathbb{C}}\left\{a^{-1} A\right\}$, (4.7) is equivalent to

$$
\operatorname{span}_{\mathbb{C}}\left\{\overline{a^{-1} B}\right\} \cap \operatorname{span}_{\mathbb{C}}\left\{a^{-1} A\right\}=\{0\}
$$

Conversely, we assume (4.6) and (4.7) hold. For any $x \in X$, taking local holomorphic coordinates $\left\{z^{\alpha}\right\}_{1 \leq \alpha \leq n}$ around $x \in X$ such that

$$
\operatorname{span}_{\mathbb{C}}\left\{\left.d z^{1}\right|_{x}, \cdots,\left.d z^{n_{0}}\right|_{x}\right\}=\operatorname{span}_{\mathbb{C}}\{\bar{B}\}
$$

and

$$
\operatorname{span}_{\mathbb{C}}\left\{\left.d z^{n_{0}+1}\right|_{x}, \cdots,\left.d z^{n_{1}}\right|_{x}\right\}=\operatorname{span}_{\mathbb{C}}\{A\}
$$

we now set

$$
U_{x}:=\operatorname{span}_{\mathbb{C}}\left\{\left.\partial_{1}\right|_{x}, \cdots,\left.\partial_{n_{0}}\right|_{x}\right\}, \quad V_{x}=\operatorname{span}_{\mathbb{C}}\left\{\left.\partial_{n_{0}+1}\right|_{x}, \cdots,\left.\partial_{n}\right|_{x}\right\}
$$

Then $U_{x} \oplus V_{x}=T_{x}^{1,0} X$. Using (4.6) and (4.7), one can check that ( $E, h^{E}$ ) is strongly decomposably non-negative.

Hence, $\left(E, h^{E}\right)$ is strongly decomposably non-negative of type I if and only if the Chern curvature matrix of ( $E, h^{E}$ ) satisfies (4.6) and (4.7).

Next, we assume that $\left(E, h^{E}\right)$ is strongly decomposably positive of type I; that is, it is strongly decomposably non-negative of type I and

$$
\begin{equation*}
R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}=0 \Longrightarrow u^{i \alpha}=0, \text { for all } 1 \leq i \leq r, 1 \leq \alpha \leq n_{0} \tag{4.8}
\end{equation*}
$$

and

$$
\begin{equation*}
R_{i \bar{j} \alpha \bar{\beta}} \bar{v}^{\bar{j} \alpha} \overline{v^{\bar{i} \beta}}=0 \Longrightarrow v^{\bar{j} \alpha}=0, \text { for all } 1 \leq j \leq r, n_{0}+1 \leq \beta \leq n \tag{4.9}
\end{equation*}
$$

By the equivalent description of strongly decomposably non-negative of type I (i.e., (4.6) and (4.7) hold), one has

$$
R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}=\sum_{p=1}^{N_{2}}\left|B_{i p \bar{\alpha}} \overline{u^{i \alpha}}\right|^{2} .
$$

Definition 4.2. Let $B$ be a $r \times N_{2}$ matrix with ( 0,1 )-forms as entries. We define the following $N_{2} \times r n_{0}$ matrix $\mathbf{B}$ as

$$
\mathbf{B}:=\left(B_{i p \bar{\alpha}}\right)_{p, i \alpha}=\left(\begin{array}{cccc}
B_{11 \overline{1}} & B_{11 \overline{2}} & \cdots & B_{r 1 \overline{n_{0}}}  \tag{4.10}\\
B_{12 \overline{1}} & B_{11 \overline{2}} & \cdots & B_{r 2 \overline{n_{0}}} \\
\vdots & \vdots & \ddots & \vdots \\
B_{1 N_{2} \overline{1}} & B_{1 N_{2} \overline{2}} & \cdots & B_{r N_{2} \overline{\bar{n}_{0}}}
\end{array}\right)_{N_{2} \times r n_{0}} .
$$

Similarly, if $A$ is a $r \times N_{1}$ matrix with (1,0)-forms as entries, we define

$$
\mathbf{A}:=\left(A_{j p \alpha}\right)_{p, j \alpha}=\left(\begin{array}{cccc}
A_{11\left(n_{0}+1\right)} & A_{11\left(n_{0}+2\right)} & \cdots & A_{r 1 n}  \tag{4.11}\\
A_{12\left(n_{0}+1\right)} & A_{11\left(n_{0}+2\right)} & \cdots & A_{r 2 n} \\
\vdots & \vdots & \ddots & \vdots \\
A_{1 N_{1}\left(n_{0}+1\right)} & A_{1 N_{1}\left(n_{0}+2\right)} & \cdots & A_{r N_{1} n}
\end{array}\right)_{N_{1} \times r\left(n-n_{0}\right)}
$$

Hence, (4.8) is equivalent to the equation $\mathbf{B} x=0$ has only zero solution. This is also equivalent to $\operatorname{rank}(\mathbf{B})=r n_{0}$. Similarly, (4.9) is equivalent to $\operatorname{rank}(\mathbf{A})=r\left(n-n_{0}\right)$.

We obtain the following.

## Theorem 4.3.

- A Hermitian vector bundle $\left(E, h^{E}\right)$ is strongly decomposably non-negative of type I if and only if (4.6) and (4.7) hold.
- A Hermitian vector bundle $\left(E, h^{E}\right)$ is strongly decomposably positive of type I if and only if (4.6) and (4.7) hold, and $\operatorname{rank}(\mathbf{A})=r \operatorname{dim} V_{x}, \operatorname{rank}(\mathbf{B})=r \operatorname{dim} U_{x}$.

As a result, we obtain the following criteria of (dual) Nakano positive vector bundles.

## Corollary 4.4.

- A Hermitian vector bundle $\left(E, h^{E}\right)$ is Nakano positive if and only if the Chern curvature matrix has the form

$$
R=-B \wedge \bar{B}^{\top}
$$

with respect to some unitary frame, where $B$ is a $r \times N$ matrix with $(0,1)$-forms as entries, and $\operatorname{rank}(\mathbf{B})=r n$.

- A Hermitian vector bundle $\left(E, h^{E}\right)$ is dual Nakano positive if and only if the Chern curvature matrix has the form

$$
R=A \wedge \bar{A}^{\top}
$$

with respect to some unitary frame, where $A$ is a $r \times N$ matrix with $(1,0)$-forms as entries, and $\operatorname{rank}(\mathbf{A})=r n$.

Remark 4.5. Note that the above corollary for dual Nakano positivity was previously observed by F. Fagioli [7, Page 13, Positivity in (Fin20)] as a statement without proof.

### 4.2. Weak positivity of Schur forms

In this subsection, we prove the weak positivity of Schur forms for strongly decomposably positive vector bundles of type I.

### 4.2.1. Schur polynomial

Each partition $\lambda \in \Lambda(k, r)$ gives rise to a Schur polynomial $P_{\lambda} \in \mathbb{Q}\left[c_{1}, \ldots, c_{r}\right]$ of degree $k$, defined as $k \times k$ determinant

$$
P_{\lambda}\left(c_{1}, \ldots, c_{r}\right)=\operatorname{det}\left(c_{\lambda_{i}-i+j}\right)_{1 \leqslant i, j \leqslant k}
$$

where by convention $c_{0}=1$ and $c_{i}=0$ if $i \notin[0, r]$.
Denote by $\mathrm{M}_{r}(\mathbb{C})$ and $\mathrm{GL}_{r}(\mathbb{C})$ the vector spaces of $r \times r$ matrices and the general linear group of degree $r$. A map $P: \mathrm{M}_{r}(\mathbb{C}) \rightarrow \mathbb{C}$ is called $\mathrm{GL}_{r}(\mathbb{C})$-invariant if it is invariant under the conjugate action of $\mathrm{GL}_{r}(\mathbb{C})$ on $\mathrm{M}_{r}(\mathbb{C})$. Now we define the following $\mathrm{GL}_{r}(\mathbb{C})$-invariant function $c_{i}: \mathrm{M}_{r}(\mathbb{C}) \rightarrow \mathbb{C}$, $i=1, \ldots, r$ by

$$
\operatorname{det}\left(I_{r}+t X\right)=\sum_{i=0}^{r} t^{i} \cdot c_{i}(X)
$$

where $I_{r}$ is the identity matrix in $\mathrm{M}_{r}(\mathbb{C})$. Then the graded ring of $\mathrm{GL}_{r}(\mathbb{C})$-invariant homogeneous polynomials on $\mathrm{M}_{r}(\mathbb{C})$, which we denote here by $\mathrm{I}(r)=\bigoplus_{k=0}^{+\infty} \mathrm{I}(r)_{k}$, is multiplicatively generated by $c_{1}, \ldots, c_{r}$.

Let $\left(E, h^{E}\right)$ be a Hermitian vector bundle; the $i$-th Chern form $c_{i}\left(E, h^{E}\right)$ is defined by

$$
c_{i}\left(E, h^{E}\right)=c_{i}\left(\frac{\sqrt{-1}}{2 \pi} R^{E}\right)
$$

For each $\lambda \in \Lambda(k, r)$, recall the Schur form (see Introduction) can be given by

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=P_{\lambda}\left(c_{1}\left(E, h^{E}\right), \ldots, c_{r}\left(E, h^{E}\right)\right)
$$

which represents the Schur class

$$
P_{\lambda}(c(E)):=P_{\lambda}\left(c_{1}(E), \ldots, c_{r}(E)\right) \in \mathrm{H}^{2 k}(X, \mathbb{Z})
$$

### 4.2.2. Griffiths cone

By [14, Page 242, (5.6)], each $P \in \mathrm{I}(r)_{k}$ can be written as

$$
\begin{equation*}
P(B)=\sum_{\sigma, \tau \in S_{k}} \sum_{\rho \in[1, r]^{k}} p_{\rho \sigma \tau} B_{\rho_{\sigma(1)} \rho_{\tau(1)}} \cdots B_{\rho_{\sigma(k)} \rho_{\tau(k)}} \tag{4.12}
\end{equation*}
$$

where $B_{\lambda \mu}, \lambda, \mu=1, \ldots, r$ are the components of the matrix $B, S_{k}$ is the permutation group on $k$ indices and $[1, r]:=\{1, \ldots, r\}$. An element $P \in \mathrm{I}(r)_{k}$ is called Griffiths non-negative if it can be expressed in the form (4.12) with

$$
p_{\rho \sigma \tau}=\sum_{t \in T} \lambda_{\rho t} \cdot q_{\rho \sigma t} \bar{q}_{\rho \tau t}
$$

for some finite set $T$, some real numbers $\lambda_{\rho t} \geqslant 0$, and complex numbers $q_{\rho \sigma t}$.
The Griffiths cone $\Pi(r) \subset \mathrm{I}(r)$ is defined as the cone of Griffiths non-negative polynomials.
Proposition 4.6 (Fulton-Lazarsfeld [11, Proposition A.3]). Let

$$
P=\sum_{\lambda \in \Lambda(k, r)} a_{\lambda}(P) P_{\lambda} \quad\left(a_{\lambda}(P) \in \mathbb{Q}\right)
$$

be a non-zero weighted homogeneous polynomial in $\mathbb{Q}\left[c_{1}, \ldots, c_{r}\right]$. Then $P$ lies in the Griffiths cone $\Pi(r)$ if and only if each of the Schur coefficients $a_{\lambda}(P)$ is non-negative.

In particular, for each $\lambda \in \Lambda(k, r)$, one has

$$
P_{\lambda}(B)=\sum_{\sigma, \tau \in S_{k}} \sum_{\rho \in[1, r]^{k}} p_{\rho \sigma \tau} B_{\rho_{\sigma(1)} \rho_{\tau(1)}} \cdots B_{\rho_{\sigma(k)} \rho_{\tau(k)}}
$$

where $p_{\rho \sigma \tau}=\sum_{1 \leq i, j \leq m}\left(\frac{1}{k!}\right)^{2} a_{i j}(\tau) \overline{a_{i j}(\sigma)}$ with $\left(a_{i j}(\tau)\right) \in \mathrm{U}(m)$, see $[11,(A .6)]$. Denote $T=[1, m]^{2}$ and $q_{\sigma t}:=\overline{a_{t}(\sigma)}$ for any $t \in T$. Then

$$
\begin{equation*}
P_{\lambda}(B)=\left(\frac{1}{k!}\right)^{2} \sum_{\sigma, \tau \in S_{k}} \sum_{\rho \in[1, r]^{k}}\left(\sum_{t \in T} q_{\sigma t} \overline{q_{\tau t}}\right) B_{\rho_{\sigma(1)} \rho_{\tau(1)}} \cdots B_{\rho_{\sigma(k)} \rho_{\tau(k)}} . \tag{4.13}
\end{equation*}
$$

### 4.2.3. Weak positivity of Schur forms

We assume that ( $E, h^{E}$ ) is a strongly decomposably positive vector bundle of type I over a complex manifold $X$. By Theorem 4.3, for any $x \in X$, there exists a decomposition $T_{x}^{1,0} X=U_{x} \oplus V_{x}$ such that the Chern curvature matrix $R$ of $\left(E, h^{E}\right)$ has the form

$$
\begin{equation*}
R=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top} \tag{4.14}
\end{equation*}
$$

with respect to a unitary frame, where $B$ is a $r \times N$ matrix with ( 0,1 )-forms in $\overline{U_{x}^{*}}$ as entries and $A$ is a $r \times N$ matrix with (1,0)-forms in $V_{x}^{*}$ as entries. Moreover, $\operatorname{rank}(\mathbf{A})=r \cdot \operatorname{dim} V_{x}, \operatorname{rank}(\mathbf{B})=r \cdot \operatorname{dim} U_{x}$.

For each $\lambda \in \Lambda(k, r)$, by (4.13), the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is given by

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{\sqrt{-1}}{2 \pi}\right)^{k} \frac{1}{(k!)^{2}} \sum_{\sigma, \tau \in S_{k}} \sum_{\rho \in[1, r]^{k}}\left(\sum_{t \in T} q_{\sigma t} \overline{q_{\tau t}}\right) \cdot \bigwedge_{j=1}^{k} R_{\rho_{\sigma(j)} \overline{\rho_{\tau(j)}}} .
$$

By (4.14), the Chern curvature matrix satisfies

$$
\begin{aligned}
R_{\rho_{\sigma(j)} \overline{\rho_{\tau(j)}}} & =\left(B_{\rho_{\tau(j)} c_{j} \overline{\beta_{j}}} \overline{B_{\rho_{\sigma(j)} c_{j} \overline{\alpha_{j}}}}+A_{\rho_{\tau(j)} c_{j} \alpha_{j}} \overline{A_{\rho_{\sigma(j)} c_{j} \beta_{j}}}\right) d z^{\alpha_{j}} \wedge d \bar{z}^{\beta_{j}} \\
& =\sum_{c_{j}=1}^{N}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}} \wedge B_{\rho_{\tau(j)} c_{j}}+A_{\rho_{\tau(j)} c_{j}} \wedge \overline{A_{\rho_{\sigma(j)} c_{j}}}\right) \\
& =\sum_{c_{j}=1}^{N} \sum_{\epsilon_{j} \in\{0,1\}}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}} \wedge B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}} \wedge \overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}},
\end{aligned}
$$

which follows that

$$
\begin{aligned}
& \bigwedge_{j=1}^{k} R_{\rho_{\sigma(j)}} \overline{\rho_{\tau(j)}}=\bigwedge_{j=1}^{k} \sum_{c_{j}=1}^{N} \sum_{\epsilon_{j} \in\{0,1\}}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}} \wedge B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}} \wedge \overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}} \\
& =\sum_{c \in[1, N]^{k}} \sum_{\epsilon \in\{0,1\}^{k}} \bigwedge_{j=1}^{k}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}} \wedge B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}} \wedge \overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}} \\
& =\sum_{c \in[1, N]^{k}} \sum_{\epsilon \in\{0,1\}^{k}} \bigwedge_{j=1}^{k}(-1)^{\epsilon_{j}+1}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}}\right)^{\epsilon_{j}} \wedge\left(\overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}} \wedge\left(B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}}\right)^{1-\epsilon_{j}} \\
& =\sum_{c \in[1, N]^{k}} \sum_{\epsilon \in\{0,1\}^{k}}(-1)^{|\epsilon|+k}(-1)^{\frac{k(k-1)}{2}} . \\
& \left(\bigwedge_{j=1}^{k}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}}\right)^{\epsilon_{j}} \wedge\left(\overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}}\right) \wedge\left(\bigwedge_{j=1}^{k}\left(B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}}\right)^{1-\epsilon_{j}}\right),
\end{aligned}
$$

where $|\epsilon|:=\sum_{j=1}^{k} \epsilon_{j}$.
Recall that $\rho \in[1, r]^{k}, t \in T, c \in[1, N]^{k}$ and $\epsilon \in\{0,1\}^{k}$. We obtain that

$$
\begin{aligned}
& P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{\sqrt{-1}}{2 \pi}\right)^{k} \frac{1}{(k!)^{2}}(-1)^{\frac{k(k-1)}{2}} \sum_{\rho, t, c, \epsilon}(-1)^{|\epsilon|+k} . \\
& \quad\left(\sum_{\sigma \in S_{k}} q_{\sigma t} \bigwedge_{j=1}^{k}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}}\right)^{\epsilon_{j}} \wedge\left(\overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}}\right) \wedge\left(\sum_{\tau \in S_{k}} \overline{q_{\tau t}} \bigwedge_{j=1}^{k}\left(B_{\rho_{\tau(j)} c_{j}}\right)^{\epsilon_{j}} \wedge\left(A_{\rho_{\tau(j)} c_{j}}\right)^{1-\epsilon_{j}}\right) .
\end{aligned}
$$

Now we set

$$
\begin{equation*}
\psi_{\rho t c \epsilon}:=\sum_{\sigma \in S_{k}} q_{\sigma t} \bigwedge_{j=1}^{k}\left(\overline{B_{\rho_{\sigma(j)} c_{j}}}\right)^{\epsilon_{j}} \wedge\left(\overline{A_{\rho_{\sigma(j)} c_{j}}}\right)^{1-\epsilon_{j}}, \tag{4.15}
\end{equation*}
$$

which is a $(|\epsilon|, k-|\epsilon|)$-form. Hence,

$$
\begin{equation*}
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{1}{2 \pi}\right)^{k}\left(\frac{1}{k!}\right)^{2}(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c, \epsilon}(-1)^{|\epsilon|+k} \psi_{\rho t c \epsilon} \wedge \overline{\psi_{\rho t c \epsilon}} . \tag{4.16}
\end{equation*}
$$

For any non-zero decomposable $(n-k, 0)$-form $\eta=\eta_{1} \wedge \cdots \wedge \eta_{n-k}$, where $\eta_{i}, 1 \leq i \leq n-k$, are ( 1,0 )-forms, we assume that $\eta_{1}, \cdots, \eta_{i_{0}} \in U_{x}^{*}$ and $\eta_{i_{0}+1}, \cdots, \eta_{n-k} \in V_{x}^{*}$. Now we can take local
holomorphic coordinates $\left\{z^{\alpha}\right\}_{1 \leq \alpha \leq n}$ around $x \in X$ such that

$$
U_{x}^{*}=\operatorname{span}_{\mathbb{C}}\left\{\left.d z^{1}\right|_{x}, \cdots,\left.d z^{n_{0}}\right|_{x}\right\}, \text { with }\left.d z^{j}\right|_{x}=\eta_{j}, \quad 1 \leq j \leq i_{0}
$$

and

$$
V_{x}^{*}=\operatorname{span}_{\mathbb{C}}\left\{\left.d z^{n_{0}+1}\right|_{x}, \cdots,\left.d z^{n}\right|_{x}\right\}, \text { with }\left.d z^{n_{0}-i_{0}+j}\right|_{x}=\eta_{j}, \quad i_{0}+1 \leq j \leq n-k,
$$

and so $\psi_{\rho t c \epsilon}$ can be written in the following form:

$$
\psi_{\rho t c \epsilon}=\sum_{\substack{1 \leq \alpha_{1}<\cdots<\alpha_{|\epsilon|} \leq n_{0} \\ n_{0}+1 \leq \beta_{1} \leq \cdots<\beta_{k-\epsilon \mid} \leq n}} \psi_{\alpha_{1} \cdots \alpha_{|\epsilon|} \bar{\beta}_{1} \cdots \bar{\beta}_{k-|\epsilon|}} d z^{\alpha_{1}} \wedge \cdots \wedge d z^{\alpha_{|\epsilon|}}
$$

$$
\wedge d \bar{z}^{\beta_{1}} \wedge \cdots \wedge d \bar{z}^{\beta_{k-|\epsilon|}}
$$

Then

$$
\begin{aligned}
&(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c, \epsilon}(-1)^{|\epsilon|+k} \psi_{\rho t c \epsilon} \wedge \overline{\psi_{\rho t c \epsilon}} \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta} \\
&=(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c,|\epsilon|=n_{0}-i_{0}}(-1)^{n_{0}-i_{0}+k}(\sqrt{-1})^{(n-k)^{2}} d z^{1} \wedge \cdots \wedge d z^{i_{0}} \wedge \\
& d z^{n_{0}+1} \wedge \cdots \wedge d z^{n-i_{0}+n-k} \wedge d \bar{z}^{1} \wedge \cdots \wedge d \bar{z}^{i_{0}} \wedge d \bar{z}^{n_{0}+1} \wedge \cdots \wedge d \bar{z}^{n-i_{0}+n-k} \wedge \\
&\left(\psi_{i_{0}+1, \cdots, n_{0}, \overline{n_{0}-i_{0}+n-k+1}, \cdots, \bar{n}} d z^{i_{0}+1} \wedge \cdots \wedge d z^{n_{0}} \wedge d \bar{z}_{0}^{n_{0}-i_{0}+n-k+1} \wedge \cdots \wedge d \bar{z}^{n}\right) \wedge \\
&\left(\overline{\left.\psi_{i_{0}+1, \cdots, n_{0}, \overline{n_{0}-i_{0}+n-k+1}, \cdots, \bar{n}} d \bar{z}^{i_{0}+1} \wedge \cdots \wedge d \bar{z}^{n_{0}} \wedge d z^{n_{0}-i_{0}+n-k+1} \wedge \cdots \wedge d z^{n}\right)}\right. \\
&=\sum_{\rho, t, c,|\epsilon|=n_{0}-i_{0}}\left|\psi_{i_{0}+1, \cdots, n_{0}, \overline{n_{0}-i_{0}+n-k+1}, \cdots, \bar{n}}\right|^{2} . \\
&(\sqrt{-1})^{n^{2}} d z^{1} \wedge \cdots \wedge d z^{n} \wedge d \bar{z}^{1} \wedge \cdots \wedge d \bar{z}^{n}
\end{aligned}
$$

which is a non-negative volume form. By (4.16), the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is weakly non-negative.
We show the weak positivity of Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ using a proof by contradiction. Specifically, we derive a contradiction when assuming $P_{\lambda}\left(c\left(E, h^{E}\right)\right) \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta}=0$.

By (4.17), one knows that

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right) \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta}=0
$$

if and only if

$$
\begin{equation*}
\psi_{i_{0}+1, \cdots, n_{0}, \overline{n_{0}-i_{0}+n-k+1}, \cdots, \bar{n}}=0 \tag{4.18}
\end{equation*}
$$

for any $\rho, t, c,|\epsilon|=n_{0}-i_{0}$.
Now we take a special vector $\epsilon=(\underbrace{1, \cdots, 1}_{n_{0}-i_{0}}, 0 \cdots, 0)$ and denote $j_{0}=n_{0}-i_{0}$, by (4.15). Then

$$
\psi_{\rho t c \epsilon}=\sum_{\sigma \in S_{k}} q_{\sigma t} \overline{B_{\rho_{\sigma(1)} c_{1}}} \wedge \cdots \wedge \overline{B_{\rho_{\sigma\left(j_{0}\right)} c_{j_{0}}}} \wedge \overline{A_{\rho_{\sigma\left(j_{0}+1\right)} c_{j_{0}+1}}} \wedge \cdots \wedge \overline{A_{\rho_{\sigma(k)} c_{k}}}
$$

Combining with (4.18), one has

$$
\begin{align*}
& 0=\psi_{i_{0}+1, \cdots, n_{0}, \overline{n_{0}-i_{0}+n-k+1}, \cdots, \bar{n}} \quad=\sum_{\tau_{1} \in S_{j_{0}}} \sum_{\tau_{2} \in S_{k-j_{0}}} \sum_{\sigma \in S_{k}} \operatorname{sgn}\left(\tau_{1}\right) \operatorname{sgn}\left(\tau_{2}\right) q_{\sigma t} . \\
& \overline{B_{\rho_{\sigma(1)} c_{1} \overline{\tau_{1}\left(i_{0}+1\right)}}} \cdots \overline{B_{\left.\rho_{\sigma\left(j_{0}\right)}\right) c_{j_{0}} \overline{\tau_{1}\left(n_{0}\right)}}} \cdot \overline{A_{\rho_{\sigma\left(j_{0}+1\right)} c_{j_{0}+1} \tau_{2}\left(j_{0}+n-k+1\right)}} \cdots \overline{A_{\rho_{\sigma(k)} c_{k} \tau_{2}(n)}} . \tag{4.19}
\end{align*}
$$

Since $\operatorname{rank}(\mathbf{A})=r \cdot \operatorname{dim} V_{x}, \operatorname{rank}(\mathbf{B})=r \cdot \operatorname{dim} U_{x}$, without loss of generality, we assume that the submatrices

$$
\mathbf{B}^{\prime}=\left(\mathbf{B}_{c, i \alpha}\right)_{1 \leq c \leq r \operatorname{dim} U_{x}, 1 \leq i \leq r, 1 \leq \alpha \leq \operatorname{dim} U_{x}}
$$

and

$$
\mathbf{A}^{\prime}=\left(\mathbf{A}_{c, j \alpha}\right)_{1 \leq c \leq r \operatorname{dim} V_{x}, 1 \leq j \leq r, 1 \leq \alpha \leq \operatorname{dim} V_{x}}
$$

of $\mathbf{B}$ and $\mathbf{A}$ are inverse. By (4.19) and note that $\mathbf{B}_{c, i \alpha}^{\prime}=B_{i c \bar{\alpha}}$ and $\mathbf{A}_{c, j \alpha}^{\prime}=A_{j c \alpha}$, one has

$$
\begin{align*}
& 0=\sum_{\tau_{1} \in S_{j_{0}}} \sum_{\tau_{2} \in S_{k-j_{0}}} \sum_{c_{1}, \cdots, c_{j_{0}}=1}^{r n_{0}} \sum_{c_{j_{0}+1}, \cdots, c_{k}=1}^{r\left(n-n_{0}\right)} \sum_{\sigma \in S_{k}} \operatorname{sgn}\left(\tau_{1}\right) \operatorname{sgn}\left(\tau_{2}\right) q_{\sigma t} . \\
& \overline{\mathbf{B}_{c_{1}, \rho_{\sigma(1)} \tau_{1}\left(i_{0}+1\right)}^{\prime}} \cdots \overline{\mathbf{B}_{c_{j_{0}}, \rho_{\sigma\left(j_{0}\right)} \tau_{1}\left(n_{0}\right)}^{\prime}} \cdot \overline{\mathbf{A}_{c_{j_{0}+1}, \rho_{\sigma\left(j_{0}+1\right)} \tau_{2}\left(j_{0}+n-k+1\right)}^{\prime}} \cdots \overline{\mathbf{A}_{c_{k}, \rho_{\sigma(k)} \tau_{2}(n)}^{\prime}} . \\
& \overline{\mathbf{A}^{\prime}-1_{l_{k} \beta_{k}, c_{k}}} \cdots \overline{\mathbf{A}^{\prime}-1_{l_{j_{0}+1} \beta_{j_{0}+1}, c_{j_{0}+1}} \mathbf{B}^{\prime}-1_{l_{j_{0}} \beta_{0}, c_{j_{0}}} \cdots \overline{\mathbf{B}^{\prime}-1_{l_{1} \beta_{1}, c_{1}}}}  \tag{4.20}\\
& \quad=\sum_{\tau_{1} \in S_{j_{0}}} \sum_{\tau_{2} \in S_{k-j_{0}}} \sum_{\sigma \in S_{k}} \operatorname{sgn}\left(\tau_{1}\right) \operatorname{sgn}\left(\tau_{2}\right) q_{\sigma t} \cdot \delta_{\rho_{\sigma(k)} l_{k}} \delta_{\tau_{2}(n) \beta_{k}} \cdots \delta_{\rho_{\sigma\left(j_{0}+1\right)} l_{j_{0}+1}} . \\
& \delta_{\tau_{2}\left(j_{0}+n-k+1\right) \beta_{j_{0}+1}} \delta_{\rho_{\sigma\left(j_{0}\right)} l_{j_{0}}} \delta_{\tau_{1}\left(n_{0}\right) \beta_{j_{0}}} \cdots \delta_{\rho_{\sigma(1)} l_{1}} \delta_{\tau_{1}\left(i_{0}+1\right) \beta_{1}}
\end{align*}
$$

for any $\left(\beta_{1}, \cdots, \beta_{j_{0}}\right) \in\left[1, n_{0}\right]^{j_{0}},\left(\beta_{j_{0}+1}, \cdots, \beta_{k}\right) \in\left[n_{0}+1, n\right]^{n-j_{0}}$ and $\left(l_{1}, \cdots, l_{k}\right) \in[1, r]^{k}$.
By taking

$$
\beta_{s}= \begin{cases}i_{0}+s & 1 \leq s \leq j_{0} \\ n-k+s & j_{0}+1 \leq s \leq k\end{cases}
$$

(4.20) becomes

$$
\begin{equation*}
\sum_{\sigma \in S_{k}} q_{\sigma t} \delta_{\rho_{\sigma(1)} l_{1}} \cdots \delta_{\rho_{\sigma(k)} l_{k}}=0 \tag{4.21}
\end{equation*}
$$

for any $\rho, l \in[1, r]^{k}$ and $t \in T$.
Remark 4.7. Note that (4.21) holds if and only if $\psi_{\rho t c \epsilon}=0$ for any $\rho, t, c, \epsilon$. In fact, if $\psi_{\rho t c \epsilon}=0$, then (4.18) holds and follows (4.21). Conversely, if (4.21) holds, then

For $k \leq r$, one can take $\rho_{i}=l_{i}=i$ for $1 \leq i \leq k$. Thus,

$$
0=\sum_{\sigma \in S_{k}} q_{\sigma t} \delta_{\rho_{\sigma(1)} l_{1}} \cdots \delta_{\rho_{\sigma(k)} l_{k}}=q_{\mathrm{Id}, t}
$$

for any $t \in T$, which is a contradiction since $\left(q_{\mathrm{Id}, t}\right)_{t \in T} \in \mathrm{U}(m)$ is a unitary matrix. Hence, all $(k, k)$-Schur forms $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ are weakly positive for any $k \leq r$. In particular, all Chern forms $c_{i}\left(E, h^{E}\right), 1 \leq i \leq r$, are weakly positive.

For general $k$ and $r$, we take $l_{1}, \cdots, l_{k}$ in (4.21) to be

$$
l_{i}=\rho_{i}, \text { for } 1 \leq i \leq k,
$$

and (4.21) implies that

$$
\begin{equation*}
\sum_{\rho \in[1, r]^{k}} \sum_{\sigma \in S_{k}} \chi_{\lambda}(\sigma) \delta_{\rho_{1} \rho_{\sigma(1)}} \cdots \delta_{\rho_{k} \rho_{\sigma(k)}}=0 \tag{4.22}
\end{equation*}
$$

where

$$
\chi_{\lambda}(\sigma)=\operatorname{Tr}\left(\overline{q_{\sigma t}}\right)=\sum_{i=1}^{m} a_{i i}(\sigma)
$$

is the character of the representation $\phi_{\lambda}(\sigma)=\left(a_{i j}(\sigma)\right) \in \mathrm{U}(m)$ corresponding to the partition $\lambda$. From [11, (A.5)], (4.22) is equivalent to

$$
\begin{equation*}
P_{\lambda}\left(I_{r}\right)=0 . \tag{4.23}
\end{equation*}
$$

Here, $P_{\lambda}(\bullet)$ denotes the invariant polynomial corresponding to the Schur function $P_{\lambda}$ under the isomorphism $\mathrm{I}(r) \cong \mathbb{Q}\left(c_{1}, \cdots, c_{r}\right)$.

Denote by $x_{1}, \cdots, x_{r}$ the Chern roots, which are defined by

$$
\sum_{j=0}^{r} c_{j} t^{j}=\left(1+t x_{1}\right)\left(1+t x_{2}\right) \cdots\left(1+t x_{r}\right)
$$

Recall that the Schur polynomial is defined by

$$
P_{\lambda}\left(c_{1}, \ldots, c_{r}\right)=\operatorname{det}\left(c_{\lambda_{j}-j+l}\right)_{1 \leqslant j, l \leqslant k},
$$

where $\lambda=\left(\lambda_{1}, \cdots, \lambda_{k}\right) \in \Lambda(k, r)$ is a partition satisfying

$$
\sum_{i=1}^{k} \lambda_{i}=k \text { and } r \geq \lambda_{1} \geq \cdots \geq \lambda_{k} \geq 0
$$

Denote by $\lambda^{\prime}$ the conjugate partition to the partition $\lambda$ (see, for example, [12, Section 4.1, Page 45]). Then

$$
\begin{equation*}
\lambda^{\prime}=\left(\lambda_{1}^{\prime}, \cdots, \lambda_{r}^{\prime}\right), \quad \text { with } \sum_{i=1}^{r} \lambda_{i}^{\prime}=k \text { and } \lambda_{1}^{\prime} \geq \cdots \geq \lambda_{r}^{\prime} \geq 0 \tag{4.24}
\end{equation*}
$$

The second Jacobi-Trudi identity (or Giambell's formula) gives

$$
\begin{equation*}
P_{\lambda}\left(c_{1}, \ldots, c_{r}\right)=\operatorname{det}\left(c_{\lambda_{j}-j+l}\right)_{1 \leqslant j, l \leqslant k}=s_{\lambda^{\prime}}\left(x_{1}, \cdots, x_{r}\right) ; \tag{4.25}
\end{equation*}
$$

see, for example, [12, Page 455, (A.6)], where

$$
s_{\chi^{\prime}}\left(x_{1}, \cdots, x_{r}\right):=\frac{\left|\begin{array}{cccc}
x_{1}^{\lambda_{1}^{\prime}+r-1} & x_{2}^{\lambda_{1}^{\prime}+r-1} & \ldots & x_{r}^{\lambda_{1}^{\prime}+r-1}  \tag{4.26}\\
x_{1}^{\lambda_{2}^{\prime}+r-2} & x_{2}^{\lambda_{2}^{\prime}+r-2} & \ldots & x_{r}^{\lambda_{2}^{\prime}+r-2} \\
\vdots & \vdots & \ddots & \vdots \\
x_{1}^{\lambda_{r}^{\prime}} & x_{2}^{\lambda_{r}^{\prime}} & \ldots & x_{r}^{\lambda_{r}^{\prime}}
\end{array}\right|}{\prod_{1 \leq i<j \leq r}\left(x_{i}-x_{j}\right)} .
$$

In particular, we have

$$
\begin{align*}
P_{\lambda}\left(I_{r}\right) & =P_{\lambda}\left(c_{1}=C_{r}^{1}, \cdots, c_{i}=C_{r}^{i}, \cdots, c_{r}=C_{r}^{r}\right) \\
& =s_{\lambda^{\prime}}(1, \cdots, 1)  \tag{4.27}\\
& =\prod_{1 \leq i<j \leq r} \frac{\lambda_{i}^{\prime}-\lambda_{j}^{\prime}+j-i}{j-i} \geq 1,
\end{align*}
$$

where the third equality follows from [12, Page 461, (ii)]. Hence, $P_{\lambda}\left(I_{r}\right) \neq 0$, which contradicts (4.23). Thus,

$$
P_{\lambda}\left(c\left(E, h^{E}\right)\right) \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta}>0
$$

for any non-zero decomposable ( $n-k, 0$ ) -form $\eta$, and so $P_{\lambda}\left(c\left(E, h^{E}\right)\right.$ ) is a weakly positive $(k, k)$-form.
We obtain the following.
Theorem 4.8. Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle of type I over a complex manifold $X, \operatorname{rank} E=r$, and $\operatorname{dim} X=n$. Then the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is weakly positive for any partition $\lambda \in \Lambda(k, r), k \leq n$ and $k \in \mathbb{N}$.

In particular, if $\left(E, h^{E}\right)$ is Nakano positive, then the Chern curvature matrix has the form

$$
R=-B \wedge \bar{B}^{\top}
$$

By considering $A=0$ in (4.15), then

$$
\psi_{\rho t c \epsilon_{1}}=\sum_{\sigma \in S_{k}} q_{\sigma t} \bigwedge_{j=1}^{k} \overline{B_{\rho_{\sigma(j)} c_{j}}}, \quad \epsilon_{1}=(1, \cdots, 1)
$$

and

$$
\psi_{\rho t c \epsilon}=0, \text { for any } \epsilon \neq \epsilon_{1} .
$$

By (4.16), one has

$$
\begin{equation*}
P_{\lambda}\left(c\left(E, h^{E}\right)\right)=\left(\frac{1}{2 \pi}\right)^{k}\left(\frac{1}{k!}\right)^{2}(\sqrt{-1})^{k^{2}} \sum_{\rho, t, c} \psi_{\rho t c \epsilon_{1}} \wedge \overline{\psi_{\rho t c \epsilon_{1}}}, \tag{4.28}
\end{equation*}
$$

where $\psi_{\rho t c \epsilon_{1}}$ is a $(k, 0)$-form. For any non-zero $(n-k, 0)$-form $\eta$, one has

$$
\begin{aligned}
& P_{\lambda}\left(c\left(E, h^{E}\right)\right) \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta} \\
= & \left(\frac{1}{2 \pi}\right)^{k}\left(\frac{1}{k!}\right)^{2}(\sqrt{-1})^{n^{2}} \sum_{\rho, t, c} \psi_{\rho t c \epsilon_{1}} \wedge \eta \wedge \overline{\psi_{\rho t c \epsilon_{1}} \wedge \eta}
\end{aligned}
$$

which is a non-negative volume form, and so $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is non-negative. Moreover,

$$
\begin{equation*}
P_{\lambda}\left(c\left(E, h^{E}\right)\right) \wedge(\sqrt{-1})^{(n-k)^{2}} \eta \wedge \bar{\eta}=0 \tag{4.29}
\end{equation*}
$$

if and only if

$$
\begin{equation*}
\psi_{\rho t c \epsilon_{1}} \wedge \eta=0 \tag{4.30}
\end{equation*}
$$

for any $\rho \in[1, r]^{k}, t \in T, c \in[1, N]^{k}$. By the expression of $\psi_{\rho t c \epsilon_{1}}$, (4.30) becomes

$$
\begin{align*}
0 & =\psi_{\rho t c \epsilon_{1}} \wedge \eta \\
& =\sum_{\sigma \in S_{k}} q_{\sigma t} \overline{B_{\rho_{\sigma(1)} c_{1}}} \wedge \cdots \wedge \overline{B_{\rho_{\sigma(k)} c_{k}}} \wedge \eta  \tag{4.31}\\
& =\sum_{\sigma \in S_{k}} q_{\sigma t} \overline{B_{\rho_{\sigma(1)} c_{1} \bar{\alpha}_{1}}} \cdots \overline{B_{\rho_{\sigma(k)} c_{k} \bar{\alpha}_{k}}} d z^{\alpha_{1}} \wedge \cdots \wedge d z^{\alpha_{k}} \wedge \eta .
\end{align*}
$$

Since ( $E, h^{E}$ ) is Nakano positive, by Corollary 4.4 , we can take $B$ such that $\mathbf{B}$ is invertible. Multiplying (4.31) by $\left(\mathbf{B}^{-1}\right)_{c_{1}, l_{1} \beta_{1}} \cdots\left(\mathbf{B}^{-1}\right)_{c_{k}, l_{k} \beta_{k}}$ and summing on $c_{1}, \cdots, c_{k}$, one has

$$
\left(\sum_{\sigma \in S_{k}} q_{\sigma t} \delta_{\rho_{\sigma(1)} l_{1}} \cdots \delta_{\rho_{\sigma(k)} l_{k}}\right) d z^{\beta_{1}} \wedge \cdots \wedge d z^{\beta_{k}} \wedge \eta=0
$$

for any $l=\left(l_{1}, \cdots, l_{k}\right) \in[1, r]^{k}$ and $\beta=\left(\beta_{1}, \cdots, \beta_{k}\right) \in[1, n]^{k}$. By choosing $\beta_{1}, \cdots, \beta_{k}$ such that $d z^{\beta_{1}} \wedge \cdots \wedge d z^{\beta_{k}} \wedge \eta \neq 0$,

$$
\begin{equation*}
\sum_{\sigma \in S_{k}} q_{\sigma t} \delta_{\rho_{\sigma(1)} l_{1}} \cdots \delta_{\rho_{\sigma(k)} l_{k}}=0 \tag{4.32}
\end{equation*}
$$

which is exactly (4.21). By Remark 4.7, (4.32) is equivalent to $\psi_{\rho t c \epsilon_{1}}=0$. Hence, (4.29) is equivalent to (4.32), which follows that $P_{\lambda}\left(I_{r}\right)=0$; see (4.23). By (4.27), $P_{\lambda}\left(I_{r}\right) \neq 0$, so we get a contradiction. Thus, $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is a positive $(k, k)$-form. Similarly, if $\left(E, h^{E}\right)$ is dual Nakano positive, then $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is also a positive $(k, k)$-form.

Hence, we can give an algebraic proof of the following positivity of Schur forms for (dual) Nakano positive vector bundles.

Theorem 4.9 (Finski [9, Theorem 1.1]). Let $\left(E, h^{E}\right)$ be a (dual) Nakano positive (respectively nonnegative) vector bundle of rank $r$ over a complex manifold $X$ of dimension $n$. Then for any $k \in \mathbb{N}, k \leqslant n$, and $\lambda \in \Lambda(k, r)$, the $(k, k)$-form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is positive (respectively non-negative).
Remark 4.10. Note that S. Finski proved the above positivity of Schur forms by using the following two steps: the first one is a refinement of the determinantal formula of Kempf-Laksov on the level of differential forms, which expresses Schur forms as a certain pushforward of the top Chern form of a Hermitian vector bundle obtained as a quotient of the tensor power of $\left(E, h^{E}\right)$, and the second one is to show the positivity of the top Chern form of a (dual) Nakano positive vector bundle. Our method here is an algebraic proof by analyzing the vanishing of Schur forms, which is very different from S. Finski's approach.

## 5. Strongly decomposable positivity of type II

In this section, we consider the strongly decomposable positivity of type II, which is the direct sum of Nakano positive and dual Nakano positive vector bundles point-wise.

### 5.1. A criterion of type II positivity

Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle of type II; see Definition 2.7. By Corollary 4.4, with respect to a unitary frame $\left\{e_{1}, \cdots, e_{r_{1}}\right\}$ of ( $E_{1, x},\left.h^{E}\right|_{E_{1, x}}$ ), and a unitary frame $\left\{e_{r_{1}+1}, \cdots, e_{r}\right\}$ of $\left(E_{2, x},\left.h^{E}\right|_{E_{2, x}}\right)$ at $x \in X$, one has

$$
\left.R_{x}^{E}\right|_{E_{1, x}}=-B_{1} \wedge{\overline{B_{1}}}^{\top},\left.\quad R_{x}^{E}\right|_{E_{2, x}}=A_{2} \wedge{\overline{A_{2}}}^{\top}
$$

with $\operatorname{rank}\left(\mathbf{B}_{1}\right)=\operatorname{dim}\left(E_{1, x}\right) \cdot n$ and $\operatorname{rank}\left(\mathbf{A}_{2}\right)=\operatorname{dim}\left(E_{2, x}\right) \cdot n$, where $B_{1}=\left(\left(B_{1}\right)_{i p}\right)_{1 \leq i \leq r_{1}, 1 \leq j \leq N_{1}}$ is a matrix with $(0,1)$-forms as entries and $A_{2}=\left(\left(A_{2}\right)_{i p}\right)_{r_{1}+1 \leq i \leq r, 1 \leq j \leq N_{2}}$ is a matrix with (1, 0 )-forms as entries. The matrices $\mathbf{B}_{1}$ and $\mathbf{A}_{2}$ are defined in (4.10) and (4.11), respectively. Now we define the matrices $A_{r \times N}$ and $B_{r \times N}\left(N=\max \left\{N_{1}, N_{2}\right\}\right)$ by

$$
B=\left(\begin{array}{cc}
B_{1} & 0  \tag{5.1}\\
0 & 0
\end{array}\right), \quad A=\left(\begin{array}{cc}
0 & 0 \\
A_{2} & 0
\end{array}\right) .
$$

Then

$$
\operatorname{rank}(\mathbf{B})=\operatorname{rank}\left(\mathbf{B}_{1}\right)=r_{1} \cdot n, \quad \operatorname{rank}(\mathbf{A})=\operatorname{rank}\left(\mathbf{A}_{2}\right)=\left(n-r_{1}\right) \cdot n
$$

and

$$
R_{x}^{E}=\left(\begin{array}{cc}
-B_{1} \wedge{\overline{B_{1}}}^{\top} & 0 \\
0 & A_{2} \wedge{\overline{A_{2}}}^{\top}
\end{array}\right)=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top} .
$$

For the matrix $\mathbf{B}=\left(B_{i p \bar{\alpha}}\right)_{i \alpha, p}$, we can associate it with another matrix $\mathcal{B}$ by

$$
\mathcal{B}=\left(\mathcal{B}_{\alpha p}\right)=\left(\sum_{i=1}^{r} B_{i p \bar{\alpha}} e_{i}\right)_{\alpha p},
$$

which is a $n \times N$ matrix with elements of $E$ as entries. Similarly, we can define a $n \times N$ matrix by

$$
\mathcal{A}=\left(\mathcal{A}_{\alpha p}\right)=\left(\sum_{i=1}^{r} A_{i p \alpha} e_{i}\right)_{\alpha p} .
$$

We define

$$
\{\mathcal{B}\}:=\left\{\sum_{i=1}^{r} B_{i p \bar{\alpha}} e_{i}, 1 \leq p \leq N, 1 \leq \alpha \leq n\right\}
$$

and

$$
\{\mathcal{A}\}:=\left\{\sum_{i=1}^{r} A_{i p \alpha} e_{i}, 1 \leq p \leq N, 1 \leq \alpha \leq n\right\} .
$$

By the definitions of the matrices $A$ and $B$, one has

$$
\operatorname{span}_{\mathbb{C}}\{\mathcal{A}\} \perp \operatorname{span}_{\mathbb{C}}\{\mathcal{B}\}
$$

Hence, if ( $E, h^{E}$ ) is a strongly decomposably positive vector bundle of type II, then there are two $r \times N$ matrices $A, B$ of $(1,0)$-forms and ( 0,1 )-forms, respectively, such that with respect to a unitary frame $\left\{e_{i}\right\}_{1 \leq i \leq r}$ of $E_{x}$,

$$
\begin{equation*}
R_{x}^{E}=-B \wedge \bar{B}^{\top}+A \wedge \bar{A}^{\top}, \tag{5.2}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{span}_{\mathbb{C}}\{\mathcal{A}\} \perp \operatorname{span}_{\mathbb{C}}\{\mathcal{B}\} \tag{5.3}
\end{equation*}
$$

Moreover, the ranks of $\mathbf{A}$ and $\mathbf{B}$ satisfy

$$
\begin{equation*}
\operatorname{rank}(\mathbf{B})=r_{1} \cdot n, \quad \operatorname{rank}(\mathbf{A})=\left(r-r_{1}\right) \cdot n . \tag{5.4}
\end{equation*}
$$

Remark 5.1. If we consider a new unitary frame $\widetilde{e}=e \cdot a$ for a unitary matrix $a \in \mathrm{U}(r)$, by Remark 4.1, one has

$$
\begin{equation*}
\widetilde{R_{x}^{E}}=-\widetilde{B} \wedge \overline{\widetilde{B}}^{\top}+\widetilde{A} \wedge \overline{\widetilde{A}}^{\top} \tag{5.5}
\end{equation*}
$$

with $\widetilde{B}=a^{-1} \cdot B$ and $\widetilde{A}=a^{-1} \cdot A$. Moreover, one has

$$
\widetilde{\mathcal{B}}_{\alpha p}=\sum_{i=1}^{r} \widetilde{B}_{i p \bar{\alpha}} \widetilde{e}_{i}=\sum_{i, j=1}^{r}\left(a^{-1}\right)_{i j} B_{j p \bar{\alpha}} \widetilde{e}_{i}=\sum_{j=1}^{r} B_{j p \bar{\alpha}} e_{j}=\mathcal{B}_{\alpha p} .
$$

Similarly, $\widetilde{\mathcal{A}}_{\alpha p}=\mathcal{A}_{\alpha p}$. Hence, $\mathcal{A}$ and $\mathcal{B}$ are independent of the unitary frame. One can also check that

$$
\operatorname{rank}(\widetilde{\mathbf{B}})=\operatorname{rank}(\mathbf{B})=r_{1} \cdot n, \quad \operatorname{rank}(\widetilde{\mathbf{A}})=\operatorname{rank}(\mathbf{A})=\left(r-r_{1}\right) \cdot n .
$$

In a word, we show that (5.2)-(5.4) hold for any unitary frame.
Conversely, we assume that (5.2)-(5.4) hold for some unitary frame of $E_{x}, x \in X$. Set

$$
E_{1, x}:=\operatorname{span}_{\mathbb{C}}\{\mathcal{B}\}, \quad E_{2, x}:=\operatorname{span}_{\mathbb{C}}\{\mathcal{A}\}
$$

Let $\left\{e_{1}, \cdots, e_{r_{1}^{\prime}}\right\}$ be a unitary frame of $E_{1, x}$ and $\left\{e_{r_{1}^{\prime}+1}, \cdots, e_{r^{\prime}}\right\}$ be a unitary frame of $E_{2, x}$. Since $E_{1, x} \perp E_{2, x}$, then $\left\{e_{i}\right\}_{1 \leq i \leq r^{\prime}}$ is a unitary frame of $E_{1, x} \oplus E_{2, x}$. Now we can extend the frame $\left\{e_{i}\right\}_{1 \leq i \leq r^{\prime}}$ and get a unitary frame $\left\{e_{i}\right\}_{1 \leq i \leq r}$ of $E_{x}$. By Remark 5.1, (5.2)-(5.4) also hold for this unitary frame $\left\{e_{i}\right\}_{1 \leq i \leq r}$. Hence,

$$
R_{i \bar{j} \alpha \bar{\beta}} e_{j} \otimes \overline{e_{i}}=\sum_{p=1}^{N}\left(-\mathcal{B}_{\beta p} \otimes \overline{\mathcal{B}_{\alpha p}}+\mathcal{A}_{\alpha p} \otimes \overline{\mathcal{A}_{\beta p}}\right)
$$

So

$$
\left.R_{x}^{E}\right|_{E_{1, x}}=-B \wedge \bar{B}^{\top},\left.R_{x}^{E}\right|_{E_{2, x}}=A \wedge \bar{A}^{\top}
$$

and

$$
R_{i \bar{j} \alpha \bar{\beta}}=0 \text { for any }(i, j) \text { or }(j, i) \in\left[1, r_{1}^{\prime}\right] \times\left[r_{1}^{\prime}+1, r\right]
$$

By (5.4), one has

$$
r_{1}^{\prime} \geq r_{1}, \quad r-r_{1}^{\prime} \geq r^{\prime}-r_{1}^{\prime} \geq r-r_{1}
$$

which follows that

$$
r_{1}=r_{1}^{\prime}, \quad r^{\prime}=r
$$

Hence, $E_{x}=E_{1, x} \oplus E_{2, x}$. By Corollary 4.4, we obtain that $R_{i \bar{j} \alpha \bar{\beta}} u^{i \alpha} \overline{u^{j \beta}}>0$ for any non-zero $u=u^{i \alpha} e_{i} \otimes \partial_{\alpha} \in E_{1, x} \otimes T_{x}^{1,0} X, R_{i \bar{j} \alpha \bar{\beta}} \nu^{i \bar{\beta}} \overline{v^{j \bar{\alpha}}}>0$ for any non-zero $v=v^{i \bar{\beta}} e_{i} \otimes \partial_{\bar{\beta}} \in E_{2, x} \otimes T_{x}^{0,1} X$. Thus, $\left(E, h^{E}\right)$ is a strongly decomposably positive vector bundle of type II.

In a word, we obtain a criterion of a strongly decomposably positive vector bundle of type II.
Theorem 5.2. ( $E, h^{E}$ ) is a strongly decomposably positive vector bundle of type II if and only if it satisfies (5.2)-(5.4).

### 5.2. Positivity of Schur forms

In this subsection, we consider the positivity of Schur forms for strongly decomposably positive vector bundles of type II.

Let $E$ and $F$ be two holomorphic vector bundles over a complex manifold $X, \operatorname{rank}(E)=r$ and $\operatorname{rank}(F)=q$. Let $x_{1}, \cdots, x_{r}$ denote the Chern roots of $E$. For any partition $\lambda^{\prime}$ satisfying (4.24), we denote

$$
s_{\lambda^{\prime}}(c(E)):=s_{\lambda^{\prime}}\left(x_{1}, \cdots, x_{r}\right) \in \mathrm{H}^{2 k}(X, \mathbb{R}),
$$

where $s_{\lambda^{\prime}}\left(x_{1}, \cdots, x_{r}\right)$ is defined in (4.26), which is also called a Schur class. Similarly, one can define the cohomology classes $s_{\lambda^{\prime}}(c(F))$ and $s_{\lambda^{\prime}}(c(E \oplus F))$. For these cohomology classes, by LittlewoodRichardson rule (see [1, Proposition 3.3 (3.14)]), one has

$$
s_{\lambda^{\prime}}(c(E \oplus F))=\sum_{\mu^{\prime}, \nu^{\prime}} c_{\mu^{\prime} v^{\prime}}^{\lambda^{\prime}} s_{\mu^{\prime}}(c(E)) s_{\nu^{\prime}}(c(F))
$$

where $c_{\mu^{\prime} \nu^{\prime}}^{\lambda^{\prime}}$ is a Littlewood-Richardson coefficient. One can refer to [10, Chapter 5] for more details on the Littlewood-Richardson coefficients. By (4.25), the Schur class $P_{\lambda}(c(E \oplus F))$ of the direct sum $E \oplus F$ satisfies

$$
\begin{equation*}
P_{\lambda}(c(E \oplus F))=\sum_{\mu^{\prime}, \nu^{\prime}} c_{\mu^{\prime} v^{\prime}}^{\lambda^{\prime}} P_{\mu}(c(E)) P_{\nu}(c(F))=\sum_{\mu, v} c_{\mu \nu}^{\lambda} P_{\mu}(c(E)) P_{\nu}(c(F)), \tag{5.6}
\end{equation*}
$$

where $\lambda, \mu, v$ are the conjugate partitions to $\lambda^{\prime}, \mu^{\prime}, v^{\prime}$, respectively. The last equality follows from the conjugation symmetry $c_{\mu^{\prime} \nu^{\prime}}^{\lambda^{\prime}}=c_{\mu \nu}^{\lambda}$; see, for example, [19, Page 115].

Let $h^{E}$ and $h^{F}$ be Hermitian metrics on $E$ and $F$, respectively. The direct sum $E \oplus F$ is equipped with the natural metric $h^{E} \oplus h^{F}$. Now we can prove (5.6) on the level of differential forms.
Proposition 5.3. For any $\lambda \in \Lambda(k, r)$, one has

$$
P_{\lambda}\left(c\left(E \oplus F, h^{E} \oplus h^{F}\right)\right)=\sum_{\mu, \nu} c_{\mu \nu}^{\lambda} P_{\mu}\left(c\left(E, h^{E}\right)\right) \wedge P_{\nu}\left(c\left(F, h^{F}\right)\right)
$$

Proof. We follow the method in the proofs of [13, Proposition 3.1] and [6, Theorem 3.5]. From the definition of total Chern form, one has

$$
c\left(E \oplus F, h^{E} \oplus h^{F}\right)=c\left(E, h^{E}\right) \wedge c\left(F, h^{F}\right)
$$

Recall that $P_{\lambda}\left(c_{1}, \ldots, c_{r}\right)=\operatorname{det}\left(c_{\lambda_{i}-i+j}\right)_{1 \leqslant i, j \leqslant k}$, so that

$$
\begin{aligned}
& P_{\lambda}\left(c\left(E \oplus F, h^{E} \oplus h^{F}\right)\right)-\sum_{\mu, v} c_{\mu \nu}^{\lambda} P_{\mu}\left(c\left(E, h^{E}\right)\right) \wedge P_{\nu}\left(c\left(F, h^{F}\right)\right) \\
& \quad=\sum_{\substack{i_{1}+2 i_{2}+\cdots+i_{i} \\
+j_{1}+2 j_{2}+\cdots q i_{q}=k}} f_{i_{1} \cdots i_{r} j_{1} \cdots j_{q}} c_{1}\left(E, h^{E}\right)^{i_{1}} \wedge \cdots \wedge c_{r}\left(E, h^{E}\right)^{i_{r}} \\
& \wedge c_{1}\left(F, h^{F}\right)^{j_{1}} \wedge \cdots \wedge c_{q}\left(F, h^{F}\right)^{j_{q}}
\end{aligned}
$$

where the universal coefficients $f_{i_{1} \cdots i_{r} j_{1} \ldots j_{q}}$ do not depend on $E, F$ and $X$, but just depend $r, q, P_{\lambda}$. By (5.6), then the cohomology class satisfies

$$
\left[\sum_{\substack{i_{1}+i_{2}+\cdots+i_{r} \\+j_{1}+2 j_{2}+\cdots+q i_{q}=k}} f_{i_{1} \cdots i_{r} j_{1} \cdots j_{q}} c_{1}\left(E, h^{E}\right)^{i_{1}} \wedge \cdots \wedge c_{r}\left(E, h^{E}\right)^{i_{r}} \wedge c_{1}\left(F, h^{F}\right)^{j_{1}} \wedge \cdots \wedge c_{q}\left(F, h^{F}\right)^{j_{q}}\right]=0
$$

Now we can take $X$ as any $n$-dimensional projective manifold and fix an ample line bundle $A$ on $X$. Let $\omega_{A}$ be a metric on $A$ with positive curvature. For $m_{1}, \cdots, m_{r}, m_{r+1}, \cdots, m_{r+q}$ positive integers, we define

$$
E=A^{\otimes m_{1}} \oplus \cdots \oplus A^{\otimes m_{r}}, \quad F=A^{\otimes m_{r+1}} \oplus \cdots \oplus A^{\otimes m_{r+q}} .
$$

By the same proof as in [6, Page 14], one can show all universal coefficients $f_{i_{1} \cdots i_{r} j_{1} \cdots j_{q}}$ vanish, which follows that

$$
P_{\lambda}\left(c\left(E \oplus F, h^{E} \oplus h^{F}\right)\right)-\sum_{\mu, \nu} c_{\mu \nu}^{\lambda} P_{\mu}\left(c\left(E, h^{E}\right)\right) \wedge P_{\nu}\left(c\left(F, h^{F}\right)\right)=0
$$

which completes the proof.
Now we assume $\left(E, h^{E}\right)$ is a strongly decomposably positive vector bundle of type II. For any $x \in X$, there exists an orthogonal decomposition of $E_{x}$,

$$
E_{x}=E_{1, x} \oplus E_{2, x}
$$

and the Chern curvature $R_{x}^{E}$ has the form

$$
R_{x}^{E}=\left(\begin{array}{cc}
\left.R_{x}^{E}\right|_{E_{1, x}} & 0 \\
0 & \left.R_{x}^{E}\right|_{E_{2, x}}
\end{array}\right)
$$

Let $\left\{e_{1}, \cdots, e_{r_{1}}\right\}$ be a unitary frame of ( $E_{1, x},\left.h^{E}\right|_{E_{1, x}}$ ) and $\left\{e_{r_{1}+1}, \cdots, e_{r}\right\}$ be a unitary frame of $\left(E_{2, x},\left.h^{E}\right|_{E_{2, x}}\right)$. Let $\left(U,\left\{z^{\alpha}\right\}_{1 \leq \alpha \leq n}\right)$ be a local coordinate neighborhood around $x$ and denote by $E_{1}=$ $U \times E_{1, x}$ the locally trivial bundle; $\left\{e_{i}\right\}_{1 \leq i \leq r_{1}}$ also gives a frame of $E_{1}$. Now we define the following Hermitian metric on $E_{1}$ by

$$
h^{E_{1}}\left(e_{i}, e_{j}\right):=\delta_{i j}-R_{i \bar{\alpha} \alpha \bar{\beta}} z^{\alpha} \bar{z}^{\beta}, \quad 1 \leq i, j \leq r_{1},
$$

which is a Hermitian metric by taking $U$ small enough. Then $\left(E_{1}, h^{E_{1}}\right)$ is a Hermitian vector bundle around $x$ and satisfies

$$
R_{x}^{E_{1}}=\left.R_{x}^{E}\right|_{E_{1, x}} .
$$

Similarly, one can define a Hermitian vector bundle $\left(E_{2}, h^{E_{2}}\right)$ such that $R_{x}^{E_{2}}=\left.R_{x}^{E}\right|_{E_{2, x}}$. Hence,

$$
\begin{aligned}
\left.c\left(E_{1} \oplus E_{2}, h^{E_{1}} \oplus h^{E_{2}}\right)\right|_{x} & =\operatorname{det}\left(\operatorname{Id}_{r}+\frac{\sqrt{-1}}{2 \pi}\left(\begin{array}{cc}
R_{x}^{E_{1}} & 0 \\
0 & R_{x}^{E_{2}}
\end{array}\right)\right) \\
& =\operatorname{det}\left(\operatorname{Id}_{r}+\frac{\sqrt{-1}}{2 \pi}\left(\begin{array}{cc}
\left.R^{E}\right|_{E_{1, x}} & 0 \\
0 & \left.R^{E}\right|_{E_{2, x}}
\end{array}\right)\right) \\
& =\operatorname{det}\left(\operatorname{Id}_{r}+\frac{\sqrt{-1}}{2 \pi} R_{x}^{E}\right. \\
& =\left.c\left(E, h^{E}\right)\right|_{x},
\end{aligned}
$$

which follows that

$$
\left.P_{\lambda}\left(c\left(E, h^{E}\right)\right)\right|_{x}=\left.P_{\lambda}\left(c\left(E_{1} \oplus E_{2}, h^{E_{1}} \oplus h^{E_{2}}\right)\right)\right|_{x}
$$

By Proposition 5.3, one has

$$
\begin{equation*}
\left.P_{\lambda}\left(c\left(E, h^{E}\right)\right)\right|_{x}=\left.\left.\sum_{\mu, \nu} c_{\mu \nu}^{\lambda} P_{\mu}\left(c\left(E_{1}, h^{E_{1}}\right)\right)\right|_{x} \wedge P_{\nu}\left(c\left(E_{2}, h^{E_{2}}\right)\right)\right|_{x} \tag{5.7}
\end{equation*}
$$

Since $\left(E_{1}, h^{E_{1}}\right)$ is Nakano positive and $\left(E_{2}, h^{E_{2}}\right)$ is dual Nakano positive at $x$, then $\left.P_{\mu}\left(c\left(E_{1}, h^{E_{1}}\right)\right)\right|_{x}$ and $\left.P_{\nu}\left(c\left(E_{2}, h^{E_{2}}\right)\right)\right|_{x}$ are positive forms. Since the Littlewood-Richardson coefficients $c_{\mu \nu}^{\lambda}$ are non-negative integers (see [10, Corollary 1 in Chapter 5]), then each summand

$$
\left.\left.c_{\mu \nu}^{\lambda} P_{\mu}\left(c\left(E_{1}, h^{E_{1}}\right)\right)\right|_{x} \wedge P_{\nu}\left(c\left(E_{2}, h^{E_{2}}\right)\right)\right|_{x}
$$

in RHS of (5.7) is non-negative. However, for any $\lambda, \mu, v$ satisfying $\lambda_{i}=\mu_{i}+v_{i}$ for all $i$, then $c_{\mu, \nu}^{\lambda}=1$ (see [10, Page 66]), and

$$
\left.\left.P_{\mu}\left(c\left(E_{1}, h^{E_{1}}\right)\right)\right|_{x} \wedge P_{\nu}\left(c\left(E_{2}, h^{E_{2}}\right)\right)\right|_{x}
$$

is a positive $(|\lambda|,|\lambda|)$-form by Proposition 3.4. By (5.7), we show that the Schur form $\left.P_{\lambda}\left(c\left(E, h^{E}\right)\right)\right|_{x}$ is a positive $(|\lambda|,|\lambda|)$-form.

Theorem 5.4. Let $\left(E, h^{E}\right)$ be a strongly decomposably positive vector bundle of type II over a complex manifold $X, \operatorname{rank} E=r$ and $\operatorname{dim} X=n$. Then the Schur form $P_{\lambda}\left(c\left(E, h^{E}\right)\right)$ is positive for any partition $\lambda \in \Lambda(k, r), k \leq n$ and $k \in \mathbb{N}$.
