Abstract:

**Background:** Equal to COVID-19 patients, non-COVID-19 patients are affected by the medical and social drawbacks of the COVID-19 pandemic. A significant reduction in elective life-changing surgeries has been witnessed in almost all affected countries. This study discusses an applicable and effective pre-operative assessment protocol that can be applied during the COVID-19 era.

**Methods:** Our study is a descriptive retrospective observational study that involves pediatric patients with CHD requiring open heart surgeries at our tertiary care center between March and November 2020. We reviewed the charts of eligible patients aged 18 years and below. We identified the total numbers of scheduled, performed, and postponed surgeries, respectively. A thorough description of the clinical and physical presentation of the postponed cases, who tested positive for SARS-CoV-2, is provided.

**Results:** 68 open heart surgeries were scheduled at our center between March and November 2020. Three surgeries (4%) were postponed due to COVID-19. The three patients were asymptomatic COVID-19 cases detected on routine SARS-CoV-2 PCR testing. No symptoms of cough, chest pain, dyspnea, rhinorrhea, diarrhea, abdominal pain, anosmia, and ageusia were reported by our patients. All patients were afebrile and hemodynamically stable. Owing to the pre-operative assessment protocol that was implemented after the first case was detected, only three healthcare workers were at risk of COVID-19 transmission and were imposed to infectious evaluation and home quarantine.

**Conclusion:** Adopting our discussed preoperative COVID-19 assessment protocol for CHD patients is an effective method to detect COVID-19 infections, optimize patient care, and ensure healthcare workers’ safety.

**Keywords:** COVID-19, CHD, pediatric patients, pre-operative assessment, surgery
1. Introduction

As of December 2019, the pandemic of COVID-19 has consisted a leading cause of significant morbidity and mortality. It has imparted substantial economic, social, and medical burdens on the global community. Unfortunately, based on the latest evidence deriving from epidemiological data and pre-clinical and clinical studies, the resolution of the pandemic cannot be warranted in the near future. Hence, physicians and healthcare professionals should remain abreast of the latest state of the pandemic and adjust their medical guidelines and policies as per the most recent updates. Meanwhile, novel strategies are needed for delivering medical care while protecting patients and medical personnel from COVID-19 infection.

Interestingly, the management of all patients in clinics and hospitals has been noticeably affected by the abrupt emergence and immense propagation of the current pandemic of COVID-19. Initially, during the first half of 2020, elective and non-emergency medical evaluations and interventions were suspended in almost all countries. At that time, surgical interventions were particularly affected due to the ambiguity of COVID-19 transmission and the need for general anesthesia and intubation in variant surgeries. These limitations have implied substantial delays in scheduling and performing surgeries. The Children’s Heart Center (CHC) at the American University of Beirut Medical Center (AUBMC) is a tertiary cardiac referral center that provides care not only for Lebanese pediatric patients but also for non-Lebanese patients referred from all over the Middle East and North Africa (MENA) region. The center is one of the chief specialized centers in MENA that is dedicated to performing congenital heart surgeries on daily basis. Up to 250 surgeries were performed annually at our center prior to COVID-19 emergence.
Shortly after the early cases of COVID-19 were declared in the country, and the total number of CHD surgeries dropped significantly between March and June 2020. Similar delay has been likely witnessed in up to 190 countries including American, Asian, European, and Middle Eastern ones.

The impact of COVID-19 on the pre-operative assessment of surgical candidates has been tackled by a few studies. Various policies have been applied in distinct medical centers. These policies are largely determined and swayed by the demographic, epidemiologic and financial states of the corresponding countries. Herein, we aspire to assess the prevalence of SARS-CoV-2 infection among pediatric cardiac patients admitted for surgical interventions at our tertiary care center. We also aim to discuss the efficacy of the COVID-19 related policy implemented at our center.

2. Methods and Material

2.1. Study Design and Population

Our retrospective single-center observational study involves a review of the charts of cardiac patients admitted to the CHC-AUBMC for open-heart surgery between March and November 2020, after the first cases of COVID-19 were declared in the country. The study population is limited to pediatric patients aged 18 years and below. No older patients are included. Patients admitted for non-surgical interventions are excluded. Similarly, patients admitted for surgery before or after the afore-mentioned period are excluded as well.
2.2. Data Collection and Analysis

Following securing Institutional Review Board Approval, we reviewed the charts of eligible patients and inspected the following parameters: age, gender, surgery type, past medical history, past surgical history, presence of COVID-19 suggestive symptoms before admission, results of SARS-CoV-2 RT PCR test, and cancellation/postponement of surgery. Similarly, we examined the results of the radiological images (i.e. chest X-RAY, chest Computed Tomography (CT) scan, and echocardiography) and the laboratory tests of the studied patients.

We identified the total number of cardiac patients admitted to our center for open-heart surgery during this period. The total numbers of both completed surgeries and postponed surgeries due to SARS-CoV-2 infection were determined as well. Our study focuses on the positive SARS-CoV-2 cases and aspires to provide a thorough discussion of their clinical presentation and COVID-19 status (asymptomatic/symptomatic, and mild/moderate/severe disease).

2.3. Study Aim

In this descriptive study, we aim to assess the prevalence of COVID-19 among cardiac pediatric patients requiring surgical interventions at our tertiary care center. Moreover, we aim to evaluate the efficacy of the newly adopted COVID-19 related policies in maintaining the quality of the delivered medical care and reducing the risk of SARS-CoV-2 transmission to patients and healthcare workers.
3. Results

A total of 68 open-heart procedures were planned at our center between March 1, 2020 and November 1, 2020. Only 3 (4.4%) procedures were postponed due to COVID-19. The remaining operations (65/68) were performed at the scheduled time after performing (1) proper screening for COVID-19 symptoms over the phone or through telehealth and (2) SARS-CoV-2 RT PCR testing for asymptomatic patients. Surgeries were delayed in all patients with COVID-19 suggestive symptoms such as cough, fever, rhinorrhea, dyspnea, headache, myalgia, anosmia or ageusia. In infants and neonates, we delayed surgery in lethargic or febrile patients having reduced activity or PO intake.

Moreover, SARS-CoV-2 PCR testing was performed to asymptomatic patients who passed symptoms screening. Surgeries were postponed in all SARS-CoV-2 positive patients. Asymptomatic patients who tested negative for SARS-CoV-2 were re-evaluated in clinic prior to the procedure, and clearance for surgery was warranted after thorough history taking and physical examination. Most of the performed surgeries were deemed essential and urgent operations that couldn’t be delayed until the COVID-19 situation is more stable. Interestingly, COVID-19 was not diagnosed postoperatively in cases with negative symptoms and SARS-CoV-2 PCR testing.

Herein, we discuss the three SARS-CoV-2 positive cases witnessed over the above-mentioned period. We describe their clinical presentation as well as their laboratory, molecular and radiological findings. We discuss also the impact of the adopted strategy on the propagation of the infection among our healthcare workers, and the delivery of necessary surgical care to our at-risk patients.
3.1. Case 1

The first patient is a male infant brought for ventricular septal defect (VSD) repair. He presented to our tertiary care center before the COVID-19 peri-operative evaluation protocol was implemented. Upon clinical and physical evaluation, history taken from the mother was negative for any signs or symptoms of infection. The patient was assessed initially by our nurses and was then examined by the pediatric cardiology fellow. Physical examination was significant for a harsh holosystolic murmur heard at the lower sternal border. Chest X-ray was only remarkable for mild enlargement in the cardiac silhouette and an increase in the pulmonary vascular markings that go with his known cardiac disease. COVID-19 PCR taken as part of the preoperative work-up was positive.

Subsequently, we consulted our infectious disease specialists who cleared the patient for discharge on strict isolation. The surgery was postponed, and the patient was monitored remotely for signs and symptoms of clinical or physical deterioration. Similarly, the team, consisting of the cardiology fellow and the two nurses who were in direct contact with the patient, were quarantined for 14 days and SARS-CoV-2 PCR tests were performed. To note, throughout the patient’s initial assessment and physical examination, our personnel were wearing the proper personal protective equipment (PPE) consisting of face mask, isolation gown, and non-sterile gloves.

The patient continued to have positive SARS-CoV-2 PCRs for 1 month. The surgery was scheduled following 1 negative PCR; however, it was not performed due to abnormal liver function tests during preoperative evaluation. Following this first case of asymptomatic COVID-19 who was detected incidentally on laboratory evaluation, we adjusted our adopted preliminary COVID-19 related policies, and we implemented the
abovementioned peri-operative assessment protocol to reduce the risk of SARS-CoV-2 transmission to healthcare workers and admitted patients who receive direct care from these workers.

3.2. Case 2

The second patient is a 3-year-old girl planned for Fontan surgery.

Before she presented to the hospital for Fontan surgery, her parents were contacted by phone and asked whether she had any COVID-19 suggestive symptoms. As per the mother, the patient had negative pre-operative assessment questionnaire. Blood tests (i.e. Complete Blood Count (CBC), and chemistry) and SARS-CoV-2 RT PCR testing were then ordered prior to in clinic evaluation as per our newly implemented pre-operative assessment protocol. CBC came back significant for a white blood cell count (WBC) of 11,000/cu.mm, and the SARS-CoV-2 PCR test was positive. The patient was asymptomatic, afebrile, and hemodynamically stable. The surgery was postponed, and she was isolated and monitored at home. The Fontan surgery was scheduled six weeks later after 2 negative SARS-CoV-2 PCRs 4 weeks apart. The surgery was smooth; however, it was difficult to wean her off the invasive ventilation postoperatively.

3.3. Case 3

The third patient is a 5-month-old female known to have tricuspid atresia, non-restrictive patent foramen ovale, and non-restrictive VSD. She was scheduled for bidirectional Glen. Her parents were contacted via phone. Pre-operative assessment questionnaire was negative. Pre-operative laboratory evaluation revealed a positive SARS-CoV-2 PCR test.
Owing to her positive PCR, the surgery was postponed, and the patient was cleared by the infectious disease team for strict home isolation with the appropriate supportive measures. The surgery was performed around four weeks later. Post-operative course was complicated by multiple episodes of desaturation and prolonged requirement of mechanical ventilation.

As for urgent cases, patients are managed medically to the maximum possible extent, while awaiting pre-operative clearance. If medical management fails, the patient is taken to surgery with full personal protective equipment for droplet and contact precautions. These patients are treated as COVID-19 positive cases. They undergo surgeries in COVID-19 specialized isolated operating rooms. These special operating rooms were designed following the pandemic and are used to perform urgent surgeries on patients who are COVID-19 positive or who have unknown COVID-19 infection status.

Following the operation, patients are placed under contact and droplet isolation until two negative COVID-19 PCR tests are obtained. As for neonates, they are placed in a separate isolation room in the neonatal intensive care unit, until two negative PCR tests are obtained.

4. Discussion

As per the COVIDSurg Collaborative Group, more than 28 million operations were cancelled or delayed globally within the first 12 weeks of the pandemic declaration, on the 11th of March 2020. Additionally, pediatric CHD surgeries were equally affected. In two separate studies evaluating the effect of COVID-19 on CHD surgeries, the number of surgeries performed...
during 2020 was almost equal to half the number performed during the pre-COVID-19 years.\textsuperscript{9,10}

Moreover, owing to the increased quest for healthcare services, the suspension of non-emergent and essential surgeries is perceived as a necessity that should be employed at any point during the course of the pandemic. Nevertheless, the need for healthcare services should not thwart the provision of essential and life-saving procedures to non-COVID-19 patients, particularly cardiac and cancer patients. These patients are already at-risk of acquiring severe and complicated COVID-19; and thus, delaying the delivery of the required medical care may weaken their immune response resulting in worsened clinical and hemodynamic conditions.

In light of the above, several congenital heart disease centers recommended adopting a patient triage that is based on surgical urgency and necessity. This triage can decrease the risk of COVID-19 transmission and ensure the delivery of emergent medical care to all patients, especially in the current era of limited medical resources.\textsuperscript{9,12,13} It can provide an effective and just distribution of the available resources among COVID-19 and non-COVID-19 patients. Stephen et al., also recommended delaying elective CHD surgeries until obtaining two negative PCR testing at least 24 hours apart.\textsuperscript{14} They endorsed prioritizing surgeries into (1) emergent surgeries that need to be performed in 48 hours from diagnosis when adequate resources are available, (2) urgent surgeries that can be performed within 2 weeks of diagnosis when resources are available, and (3) high priority elective surgery that can be performed after 2 weeks.\textsuperscript{12} Others like Dilli and Taşoğlu also suggest obtaining a SARS-CoV-2 PCR for all patients and parents.\textsuperscript{14}
Herein, between March 1 and November 1, 2020, we were able to perform 65 open heart surgeries. The performed surgeries were not restricted to urgent or emergent ones, but to the essential and life-changing surgeries that could improve the life quality of our patients. These surgeries occurred after we implemented the COVID-19 pre-operative assessment protocol consisting of (1) telehealth or over the phone symptoms screening with immediate postponement of scheduled surgeries in symptomatic patients, (2) providing SARS-CoV-2 PCR testing to all asymptomatic patients and rescheduling surgeries in SARS-CoV-2 positive patients, (3) re-evaluating asymptomatic SARS-CoV-2 negative patients in clinic, and (4) clearing afebrile and hemodynamically stable asymptomatic SARS-CoV-2 negative patients for surgeries, see **Figures 1**. To control and reduce further the in-hospital transmission of SARS-CoV-2, we limited the number of patients’ companions to one and enforced all companions to perform a SARS-CoV-2 PCR testing. Only SARS-CoV-2 negative companions were allowed to accompany the patients.

Before adjusting our original COVID-19 related policies and following the discussed pre-operative assessment protocol, one of our patients tested positive without having symptoms (case 1). The medical team members who were exposed with proper PPE to this patient were identified and quarantined for 14 days. Similarly, we provided PCR testing to all suspected in-contact personnel. However, after following the abovementioned multistep pre-operative protocol, we were able to identify preemptively two additional SARS-CoV-2 positive patients; and thus to prevent SARS-CoV-2 transmission to our healthcare workers and hospitalized patients who are in contact with our workers. Collectively, this protocol along with the appropriate use of necessary PPE
have enabled avoiding unnecessary quarantine of medical team members and preventing unexpected delays in medical care delivery to both surgical and non-surgical patients.

Interestingly, COVID-19 presentation among the three discussed CHD patients was asymptomatic. Our findings are consistent with the data available in the literature concerning disease severity and manifestations in CHD pediatric population. These patients, particularly those with complex lesions, are at-risk for acquiring severe and complicated COVID-19. However, many of them may display an asymptomatic to mild presentation. Hence, we argue that a thorough clinical evaluation should be offered to these patients, even the symptoms-free patients, to detect asymptomatic cases of COVID-19 who may silently transmit the disease not only to healthcare workers but also to in-contact hospitalized patients. Besides, in our institution, COVID-19 positive CHD patients, who are undergoing elective surgery, have to wait at least four weeks following the infection before undergoing the surgery.

Finally, protocols for international CHD patients were also derived. They should follow the country's regulations, as well as those adopted by our center. In most of the cases, the country’s regulations require one negative COVID-19 PCR test before traveling to Lebanon and another negative one post-arrival. As for our hospital regulations, in addition to adhering to the above, they should obtain a negative COVID-19 swab at least 48 hours post-arrival to Lebanon, and within 48 hours of surgery. After negative test, they should be assessed and cleared according to our pre-operative protocol.

This stepwise pre-operative evaluation protocol is cost-effective in decreasing operation cancellation and healthcare professionals’ quarantine. This newly implemented protocol is designed based on the assumption that sufficient medical equipment, staffs, and
resources are available. Moreover, following such a protocol is mandatory particularly in developing countries, like Lebanon, that are tremendously affected by the economic, social, and medical drawbacks of the pandemic. In these countries, the pre-COVID-19 medical resources are already limited by the weakened economies and medical infrastructures. This protocol allows an equitable and rationalized employment of these limited resources. For instance, our children cardiac center is a leading referral center that accepts critical cases from all over the country. Prior to March 2020, around 200 to 250 surgeries were performed annually at our center. This number was reduced to around 40% during 2020. This significant reduction is attributed to the drastic consequences and demands of the COVID-19 pandemic. In fact, even at our center that is considered one of the most equipped cardiac centers in the country, the number of available mechanical ventilators was reduced to a few owing to the increasing number of hospitalized COVID-19 patients. Nonetheless, essential highly-needed surgeries were still performed at our center owing to the adopted guidelines and policies that include the above-discussed pre-operative assessment protocol among others.

Ultimately, even with the recent promissory COVID-19 vaccine results, the path towards the end of the pandemic is still vague and might take several years. Global vaccination will prompt a decline in COVID-19 transmission. However, children, such as our patients, are not yet included in the ongoing vaccination trials. This pre-operative assessment protocol is necessary even after reaching mass vaccination to secure a COVID-19-free environment to our patients and healthcare workers.

Our study is one of a few studies discussing the impact of COVID-19 on the pre-operative evaluation of cardiac patients. It suggests an effective and easy-to-apply
protocol that attains to improving the wellbeing of the patients and reducing the risk of COVID-19 transmission among both medical workers and patients. The study is limited by the small number of enrolled patients and the inherent biases of descriptive retrospective observational studies. Similarly, our findings are certainly affected by the false negative rate of SARS-CoV-2 PCR testing that may mask the presence of additional asymptomatic COVID-19 cases. Hence, we postulate that at least two negative PCRs are needed to minimize the incidence of undetected asymptomatic COVID-19 that may remain unnoticed. Moreover, we encourage healthcare workers to adopt a step-wise patient-centered pre-operative assessment protocol, like the one discussed in our study, while dealing with at-risk populations.

5. Conclusion

The healthcare system worldwide has been significantly strained by the current ongoing pandemic of COVID-19. Nonetheless, the social and medical impacts of this pandemic should not impede the delivery of emergent and essential care to non-COVID-19 patients who are markedly affected by the current situation. As a result, amenable and easy-to-apply guidelines and policies should be implemented in all healthcare centers to secure a just distribution of medical services among COVID-19 and non-COVID-19 patients. Concerning pediatric patients with CHD, our above-mentioned protocol is deemed a safe and effective approach that identifies asymptomatic COVID-19 patients. It ensures proper performing of both emergent and non-emergent surgeries. It optimizes patient’s care during the COVID-19 era while ensuring healthcare workers’ safety.

Figure 1. Pre-operative Assessment Protocol during COVID-19 pandemic. The first step of the pre-operative assessment begins within a week of the surgery. The patient is screened for current active symptoms suggestive of COVID-19 infection via phone interview or through Telehealth*. If the patient has positive initial survey, the surgery is directly postponed. If this was not the case, the patient then performs RT-PCR test, 24-48 hours prior to surgery. If the swab result is negative, the patient is asked to come in person for pre-operative clinical assessment. In the clinic, the physician performs the required pre-operative physical examination and takes relevant history. If the patient passes all the above assessment steps, he is cleared for surgery. The pre-operative assessment questionnaire represents the set of questions used in the phone assessment.

Pre-operative Assessment Questionnaire:
- Did the patient travel recently? If yes, specify time and place.
- Has the patient been exposed to a COVID-19 positive patient recently? If yes, When?
- Has the patient been diagnosed with COVID-19 previously? If yes, When?
- Has any household member been diagnosed with COVID-19? If yes, When?
- Does the patient suffer currently from any of the following symptoms:
  - Fever – Chills – Headache
  - Rhinorrhea – Cough – Dyspnea – Chest pain
  - Diarhoea – Vomiting – Abdominal pain
  - Myalgia – Arthralgia
  - Anosmia – Ageusia
  - Lethargy – Fatigue
  - Decreased Activity
  - Decreased Oral intake
