ON THE MEDIANS OF A TRIANGLE IN HYPERBOLIC GEOMETRY

O. BOTTEMA

1. In non-Euclidean geometry the three medians of a triangle $A_1A_2A_3$ (each joining a vertex A_i with the internal midpoint G_i of the opposite side) are concurrent; their common point is the centroid G. But the Euclidean theorem

$$\frac{GG_i}{A_iG_i} = \frac{1}{3},$$

which depends on similarity, does not hold. In what follows we make some remarks on this ratio, restricting ourselves to hyperbolic geometry.

In accordance with a procedure recommended by Coxeter (1, p. 229), we take $A_1A_2A_3$ as the triangle of reference for projective co-ordinates x_1 , x_2 , x_3 ; the equation of the absolute conic Ω then appears in the general form. For our purpose we take, moreover, G as the unit-point. The equation of Ω is now

(1) $x_1^2 + x_2^2 + x_3^2 + 2 \cosh a_1 \cdot x_2 x_3 + 2 \cosh a_2 \cdot x_3 x_1 + 2 \cosh a_3 \cdot x_1 x_2 = 0$, where a_i is the length of the side opposite A_i . The tangential equation of Ω reads

 $\sinh^2 a_1 \cdot u_1^2 + \sinh^2 a_2 \cdot u_2^2 + \sinh^2 a_3 \cdot u_3^2 + 2(\cosh a_1 - \cosh a_2 \cdot \cosh a_3) u_2 u_3$ (2) + 2(\cosh a_2 - \cosh a_3 \cdot \cosh a_1) u_3 u_1 + 2(\cosh a_3 - \cosh a_1 \cdot \cosh a_2) u_1 u_2 = 0.

From A_i being inside Ω follows the inequality (1, p. 239)

- (3) $\gamma \equiv 2 \cosh a_1 \cdot \cosh a_2 \cdot \cosh a_3 \cosh^2 a_1 \cosh^2 a_2 \cosh^2 a_3 + 1 > 0$, which is equivalent with the fact that a side of the triangle is less than the sum of the other two.
- **2.** The median A_3G_3 has the equations $x_1 = x_2 = \lambda$, $x_3 = 1$, where λ is a parameter; for $\lambda = \infty$, 0, 1 we have the points G_3 , A_3 , G. The points of intersection S_1 and S_2 of the median and the absolute are given by the roots λ_1 , λ_2 of the equation

(4)
$$2\lambda^2(1+b_3)+2(b_1+b_2)\lambda+1=0,$$

where b_i is written for cosh a_i . Both roots are negative. We put $\mu_i = -\lambda_i$, $\mu_2 > \mu_1$, $A_iG_i = z_i$, $GG_i = y_i$. Then

Received March 3, 1958.

$$z_3 = \frac{1}{2} \log (S_1 S_2 A_3 G_3), y_3 = \frac{1}{2} \log (S_1 S_2 G G_3)$$

or

$$e^{2z_3} = \frac{\mu_2}{\mu_1}, \qquad e^{2y_3} = \frac{\mu_2 + 1}{\mu_1 + 1}.$$

Hence

and

(6)
$$\tanh y_3 = \frac{\mu_2 - \mu_1}{\mu_2 + \mu_1 + 2} = \frac{\sqrt{[\mu_1 \mu_2]} \cdot \sinh z_3}{\sqrt{[\mu_1 \mu_2]} \cosh z_3 + 1}.$$

Furthermore,

(7)
$$\mu_1 \mu_2 = \lambda_1 \lambda_2 = \frac{1}{2(1+b_3)} = \frac{1}{4 \cosh^2 \frac{1}{2} a_3},$$

and so we get the following formulae:

(8)
$$(\mu_1 + 1)(\mu_2 + 1) = \frac{2(b_1 + b_2 + b_3) + 3}{2(1 + b_3)},$$

(9)
$$\cosh z_3 = \frac{\cosh a_1 + \cosh a_2}{2 \cosh \frac{1}{2} a_3},$$

(10)
$$\frac{\sinh y_3}{\sinh z_3} = \frac{1}{\{2(b_1 + b_2 + b_3) + 3\}^{\frac{1}{2}}},$$

(11)
$$\tanh y_3 = \frac{\sinh z_3}{\cosh z_3 + 2 \cosh \frac{1}{2} a_3}.$$

3. In (9) we have the well-known formula giving the length of a median as a function of the sides. From (10) it follows that

If A_iG_i are the medians of the triangle $A_1A_2A_3$, and G is the centroid, then

$$\frac{\sinh GG_1}{\sinh A_1G_1} = \frac{\sinh GG_2}{\sinh A_2G_2} = \frac{\sinh GG_3}{\sinh A_3G_3};$$

the common value of the three ratios is $\{2(\cosh a_1 + \cosh a_2 + \cosh a_3) + 3\}^{-\frac{1}{2}}$.

4. From (11) it is seen that y_3 is a function of z_3 and a_3 only. Therefore:

If for the triangle $A_1A_2A_3$ the base A_1A_2 and the length of the median A_3G_3 are given then GG_3 has a fixed value.

If for abbreviation we denote $p_i = 2 \cosh \frac{1}{2}a_i$, we have (suppressing the index *i*):

(12)
$$\tanh y = \frac{\sinh z}{\cosh z + \rho}.$$

504 O. BOTTEMA

Obviously y = 0 for z = 0. Furthermore, differentiating the formula we get

$$\frac{1}{\cosh^2 y} \cdot \frac{dy}{dz} = \frac{1 + p \cosh z}{\left(\cosh z + p\right)^2}$$

or

(13)
$$\frac{dy}{dz} = \frac{1 + p \cosh z}{1 + p^2 + 2p \cosh z}.$$

Hence dy/dz is an increasing function of z; for z = 0 we have

$$\frac{dy}{dz} = \frac{1}{1+p} \; ;$$

its limit for $z \to \infty$ is $\frac{1}{2}$. Therefore:

If the base $A_1A_2 = a_3$ of the triangle is fixed, then GG_3/A_3G_3 increases if A_3G_3 increases and we have the inequality

$$\frac{1}{1 + 2\cosh\frac{1}{2}a_3} < \frac{GG_3}{A_3G_3} < \frac{1}{2}.$$

As a consequence we have for all triangles the inequality

$$0 < \frac{GG_3}{A_3G_3} < \frac{1}{2}.$$

It follows from the proof that the limits in (14) and (15) cannot be sharpened.

5. The Euclidean value $\frac{1}{3}$ is between the limits given in (15). Therefore there are triangles for which

$$\frac{GG_3}{A_2G_2} = \frac{1}{3}.$$

If in (12) we put z = 3y, we get

$$\tanh y = \frac{\sinh 3y}{\cosh 3y + p}.$$

Substituting $\sinh 3y = \sinh y(4\cosh^2 y - 1)$, $\cosh 3y = \cosh y(4\cosh^2 y - 3)$, we get

$$\cosh y = \frac{1}{2}p = \cosh \frac{1}{2}a$$

Therefore: In the triangle $A_1A_2A_3$ we have

$$\frac{GG_3}{A_3G_3} = \frac{1}{3}$$

if and only if $GG_3 = \frac{1}{2}A_1A_2$; hence in the triangle A_1GA_2 the angle $\angle A_2GA_1$ is the sum of $\angle GA_1A_2$ and $\angle A_1A_2G$.

6. In such a triangle we have

$$z_3 = \frac{3}{2}a_3$$
, $\cosh z_3 = \cosh \frac{a_3}{2} \left(4\cosh^2 \frac{a_3}{2} - 3 \right)$

and therefore, in view of (9)

(16)
$$2\cosh^2 a_3 + \cosh a_3 - \cosh a_1 - \cosh a_2 - 1 = 0.$$

More generally, if

$$(17) k_3 = 2b_3^2 + b_3 - b_1 - b_2 - 1,$$

we have

$$\frac{y_3}{z_3} > \frac{1}{3}$$
, $\frac{y_3}{z_3} = \frac{1}{3}$, $\frac{y_3}{z_3} < \frac{1}{3}$

according as $k_3 < 0$, $k_3 = 0$, $k_3 > 0$, respectively. If $b_1 = b_2 = b_3$ we have obviously $k_3 > 0$. Hence in an equilateral triangle the ratios y_i/z_i are less than $\frac{1}{3}$. We define k_1 and k_2 analogously to (17). If we put $c_i = b_i + 1$ we get

$$k_1 = 2c_1^2 + 5c_1 - c_2 - c_3.$$

Hence $k_1 + k_2 + k_3 = 2(c_1^2 + c_2^2 + c_3^2) + 3(c_1 + c_2 + c_3) > 0$, since $c_i > 0$. Therefore $k_1 = k_2 = k_3 = 0$ is impossible: There are no triangles for which the three ratios y_i/z_i are $\frac{1}{3}$.

We have

(18)
$$k_1 - k_2 = 2(c_1 - c_2)(c_1 + c_2 + 3).$$

If $k_1 = k = 0$, then $c_1 = c_2$, $b_1 = b_2 = b$, $b_3 = 2b^2 - 1$; but then γ is zero and the inequality (3) is not satisfied. Therefore,

There are no triangles for which two ratios y_i/z_i are $\frac{1}{3}$.

From (18) it follows that $k_1 > k_2$ implies $c_1 > c_2$ (so that $a_1 > a_2$) and conversely.

We have established the existence of triangles for which one of the ratios y_i/z_i is $\frac{1}{3}$. Suppose $k_3 = 0$. Then $c_1 + c_2 = 2c_3^2 + 5c_3$. Moreover, we have

$$\gamma = 2c_1c_2c_3 + 2c_3(c_1 + c_2) - (c_1 + c_2)^2 + 4c_1c_2 - c_3^2 > 0$$

or

$$c_1c_2(c_3+2) > 2c_3^4 + 8c_3^3 + 8c_3^2$$
,

that is,

$$c_1c_2 > 2c_3^2(c_3+2).$$

It follows from this that

$$(c_1 - c_2)^2 < c_3^2 (2c_2 + 3)^2$$
.

Therefore, assuming $c_1 \ge c_2$, we have $c_1 - c_2 < c_3(2c_3 + 3)$, and from $c_1 + c_2 = 2c_3^2 + 5c_3$ it follows that $c_1 \ge c_2 > c_3$. Hence

If in a triangle

$$\frac{y_i}{z_i} = \frac{1}{3}$$

then a_i is smaller than each of the two other sides.

In view of all this we have: In a triangle either all three ratios y_i/z_i are less than $\frac{1}{3}$ or two of them are $<\frac{1}{3}$ and the third (belonging to the smallest side) $\geqslant \frac{1}{3}$.
