19 associated deaths in the SMD group and 4945 (0.06%) in the control group, corresponding to an OR of 1.98 (CI 1.66-2.35; p < 0.001). The odds were fourfold in the age group between 60 and 79 years. Cardiovascular diseases increased the odds by 50%. Individuals with SMD without any of the risk factors under study had three-folds odds of COVID-19 associated death.

Conclusions: Our preliminary results suggest that individuals with SMD are a further group at increased risk of COVID-19 associated death. The factors contributing to this increased mortality risk require clarification.

Introduction: Many people think that people with mental disor- ders might be dangerous or unpredictable. These patients face various sources of disadvantages and experience discrimination in job interviews, in education, and housing. Mental health-related stigma occurs not only within the public community, it is a growing issue among professionals as well. Our study is the first that investigates the stigmatising attitude of psychiatrists across Europe.

Objectives: We designed a cross-sectional, observational, multi- centre, international study of 33 European countries to investigate the attitude towards patients among medical specialists and trainees in the field of general adult and child and adolescent psychiatry.

Methods: An internet-based, anonymous survey will measure the stigmatising attitude by using the local version of the Opening Minds Stigma Scale for Health Care Providers. Data gathering started in July this year and will continue until December 2020.

Results: This study will be the first to describe the stigmatising attitude of psychiatric practitioners across Europe from their perspectives.

Conclusions: The study will contribute to knowledge of gaps in stigmatising attitude towards people with mental health problems and will provide with new directions in anti-stigma interventions.

Disclosure: No significant relationships.

24-hour movement behaviours and the risk of common mental health symptoms: A compositional analysis in the UK biobank

A. Kandola1*, B. Del Pozo Cruz2, D. Osborn1, B. Stubbs3, K. Choi1 and J. Hayes1

1Division Of Psychiatry, University College London, London, United Kingdom; 2Institute For Positive Psychology And Education, Australian Catholic University, Sydney, Australia; 3Institute Of
Introduction: Sedentary behaviour is potentially a modifiable risk factor for depression and anxiety disorders, but findings have been inconsistent.

Objectives: To assess associations of sedentary behavior with depression and anxiety symptoms and estimate the impact of replacing daily time spent in sedentary behaviors with sleep, light, or moderate-to-vigorous physical activity, using novel compositional data analysis methods.

Methods: Prospective cohort study in with 60,235 UK Biobank participants (mean age: 56; 56% female). Exposure was baseline daily movement behaviours (accelerometer-assessed sedentary behaviour, physical activity, and self-reported total sleep). Outcomes were depression and anxiety symptoms (Patient Health Questionnaire-9 and Generalised Anxiety Disorders-7) at follow-up.

Results: Replacing 60 minutes of sedentary behaviour with light activity, moderate-to-vigorous activity, and sleep was associated with lower depression symptom scores by 1.3% (95% CI, 0.4%-2.1%), 1.2% (95% CI, 1.1%-2.3%), and 1.6% (95% CI, 1.2%-2.3%), and lower odds of depression by 0.95 (95% CI, 0.94-0.96), 0.75 (95% CI, 0.74-0.76), and 0.90 (95% CI, 0.89-0.91) at follow-up. Replacing 60 minutes of sedentary behaviour with moderate-to-vigorous activity and sleep was associated with lower anxiety symptom scores by 6.8% (95% CI, 5.5%-7.6%) and 4.5% (95% CI, 3.7%-5.2%), and lower odds of meeting the threshold for an anxiety disorder by 0.90 (95% CI, 0.89-0.90) and 0.97 (95% CI, 0.96-0.97) at follow-up. However, replacing 60 minutes of sedentary behaviour with light activity was associated with higher anxiety symptom scores by 4.6% (95% CI, 3.7%-5.3%) and higher odds of an anxiety disorder by 1.07 (95% CI, 1.06-1.08).

Conclusions: Sedentary behaviour is a risk factor for increased depression and anxiety symptoms in adults, but different replacement activities differentially influence mental health.

Disclosure: No significant relationships.

Introduction: The psychiatric care paradigm has shifted towards community-centered models. Yet, prolonged hospitalizations are still a reality, with debated impact at healthcare systems and patients.

Objectives: This work aims to describe prolonged hospitalizations in acute psychiatric wards through patients' sociodemographic and clinical data.
