# SKY SURVEY OF FLARE STARS AND VARIABLE STARS - a SUMMARY OF TVELVE YEARS' COOPERATIVE OBSERVATION 

Sun Yili Tong Jianhua<br>Beijing Astronomical Observatory, China

#### Abstract

S

We lave been observing in the Sco-Opla dark cloud region for 12 years. We have only reduced a small part of the plates. Nevertheless, 12 new flare stars and more than 40 new variables stars have been found. Besides, we have discovered a new subgroup of RR stars in the globular cluster M4.

## TEXT

At present, it is well Known that compact IR sources, T Tan stars, flare stars and Orion popmation variables etc. are young stars. Observations have shown that they are always born in groups and have close relations with clusters, associations and the surrounding nebulosities where tyey were born. Both theory and observation have shown they are pre-main sequence stars and still in the process of gravitational contraction. So, it is meaningful to do a systematic survey for these stars. This is the observational approach to the problem of star formation and evolution.

In 1975, the Purple Mountain Observatory began to seaych for new flare stars and variable stars in the Sco-Oph region. Later, a cooperative group consisting of members from Shanghai, Beijing and Purple Mountain Observatories was formed. Using mainly the $60 / 90 \mathrm{~cm}$ Schnidt, the 40 cm double astrograph as well as other reflectors, we have been observing in the Sco-Oph, NGC 7000, W3 and Tan dark cloud regions for 12 years. By now more than 2000 plates have been obtained (the total exposure time $>1200$ hours ). We have only reduced a small part of the plates owing to lack of an advanced measuring machine and a computer in the past. Nevertheless, 12 new flare stars and more than 40 new variable stars have been fomed. However, more new variable stars are waiting to be measured, and even more plates are waiting to be reduced. Besides, using the UK Schmidt, we have found 62 new $H_{a}$ emission-line stars in the $\rho$ Oph region. We have also observed the slit spectra of more than 30 known T Tau stars.

Owing to the fact that the globular cluster M4 was used by us as the calibration cluster, it was blinked and measured frequently. In this process, as a by-produc!, 5 new normal RR Lyrae variables were found. Even more Important, a new subgroup of low ann intude variable stars which are located around the horizontal branch (IIB) were discovered. Their amplitudes are less than $0^{m} .1$ and main period < $0.2 d$. According to their characteristics of light variation, we can classify them as RRd-a a new subgroup of RR Lyrae stars. Beside, some periodic variables which are located in the middle part of the red giant branch (RGB) and at the intersection of IIB and RGB were found. They are remarkable in having a 98 - minute period. It is very likely that all of them are indeed chaster members.

Table 1 New Flare Stars

|  | ZB No. | a 1050 | $\delta 1950$ | Amplitude | Date |
| :---: | :---: | :---: | :---: | :---: | :---: |
