**Methods:** We recorded resting-state EEG in fourteen participants with high Beck Depression Inventory score (24.4 ± 9.7; 20.4 ± 1.5 yr. o.; 14 females; 1 left-handed) and fourteen participants with a low score (6.8 ± 3.7; 21.3 ± 2.0 y.o.; 8 females; 1 left-handed). We applied weighted phase-lag index (wPLI) to construct functional networks at sensors and sources levels and computed characteristic path length (CPL), clustering coefficient (CC), index of modularity (Q), small-world index (SWI) in 4-8, 8-13, 13-30, and 4-30 Hz frequency bands. We used Mann-Whitney U-test (p < 0.05) to investigate between-group differences in the graph metrics.

**Results:** The depressive sample was characterized by increased CC and Q in the 4-30 Hz band networks and decreased CPL in the beta-band network (sensors-level for CPL and CC, and sources-level for Q).

**Conclusions:** Elevated CC and Q may relate to an increase of intramodular connectivity, and CPL reduction reflects the global connectivity increasing. We hypothesize that intramodular hyperconnectivity could explain the rise of functional connectivity in participants with depressive symptoms. **Introduction:** Brain lesions may induce psychiatric symptoms in some cases. Imaging tests are important to make a differential diagnosis, and therefore initiate an appropriate treatment.

**Objectives:** Presentation of a clinical case about a patient with psychiatric symptoms who presented an organic lesion.

**Methods:** Bibliographic review including the latest articles in Pubmed about psychiatric symptoms induced by organic lesions.

**Results:** We present a 51-year-old male patient, with adequate previous functionality, who attended psychiatric consultations due to changes in his character, with delusional mystical and megalomanic ideation, verbiage, hypoprosexia, memory loss and insomnia (diagnosed with Bipolar Disorder type II, hypomanic episode). Eventually, a brain computed tomography scan was performed, in which meningioma was visualized. The patient underwent surgery, and he asked to keep a sample of his tumor to always carry it with him on a pendant. Psychiatric symptoms induced by organic lesions are highly variable, depending on the location and size of the lesion, and they may be the first and/or only symptom of a meningioma (up to 21% according to various studies), so it is important to perform imaging tests in some cases. At this time, the patient is under follow-up, he has remained euthymic and stable, and he refuses to take psychopharmacological medication.
Conclusions: Psychiatric symptoms may be the first and/or only manifestation of an organic lesion in some cases. Neuroimaging tests (CT and MR) may be useful in the differential diagnosis. It is important to carry out an individualized treatment based on the patient’s pathology, which may include surgery and/or drugs.

Introduction: Uterine cancer is the most common gynecologic malignant neoplasm in developed countries. While depression is up to 3-5 times more common in patients with cancer than in the general population, literature is still limited regarding the relation between Endometrial Cancer and depression.

Methods: A retrospective observational study was conducted using administrative data from all hospitalizations in Portuguese mainland public hospitals between 2008-2015. All women’s hospitalizations (≥18 years) with a primary diagnosis of Endometrial Cancer (ICD-9-CM 182.x) were selected. Secondary diagnosis of depression was identified with ICD-9-CM 296.2x, 296.3x and 311x codes. Surgical procedures codes 68.4x, 65.6x, 40.3x, 40.5x, 68.6x, 68.9x and 68.8x were used to divide the hospitalizations into surgical vs non-surgical. Groups were compared with Pearson Chi-square test and crude odds ratio (OR) was used to estimate the association between surgery and depression.

Results: From 10227 hospitalizations with a primary diagnosis of Endometrial Cancer, 533 had a registry of depression (5.2%). Annual depression frequency rose from 2.0% (2008) to 8.3% (2015). Among patients with a record of depression, 73.2% had surgery. Women who had surgery were significantly more likely to have registered depression (p<0.001). The OR for depression in surgical vs non-surgical patients was 1.73 (95%CI:1.42-2.10).

Conclusions: Patients hospitalized due to Endometrial Cancer and submitted to surgery had almost two-fold more risk of having a registry of depression. This trend reinforces the importance of early depression screening of these patients, enabling the implementation of timely therapeutic strategies before and after surgery.

doi: 10.1192/j.eurpsy.2022.561

Introduction: Individual attitudes and structural inadequacies act as major barriers towards non-utilization of cancer screening and treatment offers in many high-income countries with subsidized public healthcare.

Objectives: Our interdisciplinary research group at Heidelberg University is studying the underlying individual perceptions, attitudes and experiences of age- and gender-specific barriers against cancer-related medical and psychosocial offers available in Germany.

Methods: We designed a mixed-methods, sequential explanatory study using two quantitative instruments to determine the most important age- and gender-specific barriers for non-patients and cancer patients and survivors. In the second phase, semi-structured interviews will be conducted via selective sampling to record participant opinions, experiences and expectations of using cancer-related health services.
