Therapy and Family Therapy were the election treatment with good outcomes. The patient was released after 3 months of follow-up.

**Conclusions:** TID treatment entails lifestyle changes and self-control, which may be stressful and challenging for adolescents and their families, causing mental health problems. Since learning self-care and emotional coping strategies can improve both psychological well-being and glucose management, an interdisciplinary approach including psychological care, especially on the onset, can be crucial.

**Introduction:** The Covid-19 pandemic has had a significant impact on the mental health of adolescents. Several descriptive studies and systematic reviews have shown an increase in suicide rates in this age group.

**Objectives:** - To present a literary review on the impact of the Covid-19 pandemic on the mental health and suicidal behavior of adolescents around the world. - To present data on admission rates due to suicidal behavior during the first year of the Covid-19 pandemic in a Spanish child-adolescent psychiatric hospitalization unit.

**Methods:** - We will present a literature review and a retrospective cross-sectional study on admission rates for suicidal behavior in a child-adolescent psychiatric hospitalization unit. - Admission rates for suicidal behavior during the year prior to the pandemic will be compared with rates relative to the first year of the pandemic.

**Results:** - We have found a significant increase in admission rates for suicidal behavior during the year of the pandemic. Similar results have been found in different studies and meta-analyses. - The socio-demographic characteristics of the patients are quite similar in the two periods of time analyzed, but the reference to intra-family problems has been more frequent in the year of the pandemic.

**Conclusions:** Our data is in line with other studies suggesting that the Covid-19 pandemic has had a strong impact on teenage suicidal behavior.

**Compensation Possibilities of Mental Disorders — Individual Case of a Child with Severe Neurological Disorder**

Y. Fedorova, N. Burlakova* and Y. Mikadze

Lomonosov Moscow State University, Faculty of Psychology, Department Of Neuro- And Pathopsychology, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2022.1108

**Introduction:** Neurological diseases often lead to mental disorders in children. After the structure of disorder is identified, an important task is to examine the abilities to compensate developmental delay (Lev S. Vygotsky).

**Objectives:** The goal of the study was to explore potential of children with opsoclonus-myoclonus syndrome (OMS), which is important for psychocorrection.

**Methods:** Case study of a boy with idiopathic OMS (aged 3 years 5 months) who was patient at the Psychoneurological Department no. 2 of the Russian Children Clinical Hospital. The following methods were used: analysis of anamnestic data, analysis of patient’s medical record, pathopsychological assessment.

**Results:** Anamnestic data and medical records indicate the absence of pregnancy pathologies and normal early development. OMS was first detected when the child was aged 2 y. 7 m. Pathopsychological assessment gave the following results: 1) movement disorder (primary disorder) leads to secondary mental disorders; 2) locomotor activity disorders inhibit the child’s use of space and orientation of body in it; 3) secondary defects are detected in constructive activity, speech and drawing. Intact components of the mental processes: 1) the child demonstrates motivation for independent activity despite operational difficulties; 2) in certain activities, the general plan of actions remains intact, i.e., the goal set is actualized in movements and actions; 3) notions about objects, actions with them, planning and performance of movements are intact.

**Conclusions:** The research demonstrates disbalance between operational difficulties and integrity of semantic orientation, internal planning of actions. The data prove the importance of discussion on abilities of children with OMS to compensate mental disorders.

**Menke-Hennekam syndrome I: A Case Report**

M. Trusmei* and M. Budisteanu

University Titu Maiorescu, Faculty Of Medicine, bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2022.1109

**Introduction:** Menke–Hennekam syndrome (MHS) is a relatively new genetic condition characterized by intellectual disabilities, autistic behavior, auditory defects, recurrent upper respiratory tract infections, microcephaly and short stature. Facial characteristics include short palpebral fissures, telecanthus, depressed nasal
Results: Psychosis and schizotypy are linked historically and phe-
nomenologically, which is evidenced by their placement in non-
affective psychosis in the ICD-10 and DSM-5, and it is known that the
direct observation (by clinicians or family members) during the
childhood and adolescence are key for a correct diagnosis. In fact,
this construct reflects a phenotypic expression of vulnerability to
schizophrenia, and during childhood or adolescence it may be
understood as an early mental risk state.

Conclusions: In contrast to models of psychosis that mainly rely on
positive features and assume a progression of them, the positive
traits of schizotypy seem to be beneficial and related to a “benign or
happy schizotypy” according to the articles we reviewed.

doi: 10.1192/j.eurpsy.2022.1111

Introduction: Although autism is only twice more common in men
than women in general population, in clinical samples women are
underrepresented. This difference may be due to a poor sensitivity
of current diagnostic criteria of autism related to females. We present
a 13-year-old woman referred to the adolescent psychiatric unit for
anxiety, self injuries and suicidal ideation. After careful assessment of
current symptoms and neurodevelopmental milestones, deficits in
emotional-comunicational reciprocity, nonverbal communication and
relationships emerged, as well as inflexible adherence to routines and
restricted interests. The diagnose of autism spectrum disorder was
made and the patient started a specific treatment.

Objectives: To review the clinical features of autism spectrum
disorders in adolescent females and its differential diagnosis.

Methods: Review of the literature on autism spectrum disorders in
female and its specific features.

Results: The “Female Autism Phenotype” is a group features that
are more common in autistic women, as opposed to the classic
symptoms of autism in men. Some of these differential character-
istics are: fewer social impairments and higher levels of social
motivation; more age and gender appropriate restricted and repeti-
tive interests; more internalizing rather than externalizing symp-
toms; and a tendency towards camouflageing

Conclusions: - Autism in women is frequently underdiagnosed. -
Females express autism in ways that not always meet the current
diagnostic criteria. - The “Female Autism Phenotype” has been
proposed as an specific way of expression of autism in females.

Disclosure: No significant relationships.
