P01.89
APPLYING THE WORK OF WILFRED BION TO THE
TREATMENT OF PSYCHOTIC ADOLESCENTS
S.M. Stein. Department of Child and Adolescent Mental Health
Service, Bedfordshire and Luton Community NHS Trust. Dunstable
Health Centre. Priory Gardens. Dunstable LU6 3SU. UK

Wilfred Bion played an important role in developing modern
psychoanalytical approaches to psychotic phenomena. He developed
tree key theories in relation to the treatment of psychotic
patients including: the concept of a non-psychotic part of the
personality, the concrete nature of psychotic thinking and maternal
reverie. The first concept postulates that psychotic patients will
always have a non-psychotic part of the personality with which
the therapist can make contact. In contrast psychotic drinking
is inflexible and magical, and the therapist is obliged to operate
in a concrete manner taking account of internally-generated
explanations. The third concept requires the therapist to remain
the unmanageable experiences of the patient until such time as
they can be returned in an appropriate manner which facilitates
individualization and development. Bion's approach provides a model
for understanding psychotic patients but is limited in regard to
its practical applicability. Within this multifaceted description of
psychiatric experience, the therapist would have to provide a range
of very different therapeutic experiences including containment of
the patient's infantile self, an understanding of a childlike frame
of mind, and providing the patient with the opportunity to be
treated like a responsible adult. The paper will discuss Bion's key
concepts relating to the understanding and treatment of psychosis,
and discuss how these approaches can be applied in a practical and
user-friendly manner within a multi-disciplinary in-patient clinical
setting.

EFFECTS OF CLOZAPINE ON AUTONOMIC FUNCTIONS:
NON-INVASIVE BIOMONITORING FROM THE SKIN
Schleifweg, D-91413 Neustadt an der Aisch, Germany

Intro: Clozapine has strong anticholinergic and antiadrenergic
properties and therefore it exerts side effects such as increased
heart rate and orthostatic hypotension. We performed a clinical
study to evaluate the impact of clozapine on autonomic control of
the heart, acral vessels, and sweat glands.

Methods: Autonomic measurements from 25 patients suffering
from schizophrenia (age 18–58 years) receiving by the mean 400
mg Clozapine p.d. for at least 4 weeks, were compared with
data from 25 healthy subjects. Parameters of heart rate variability,
skin blood flow, and skin conductance were assessed. Autonomic
responses of vessels and sweat glands were provoked by a single
deep breath, which causes brief acral vasoconstriction (VC) and
increase of perspiration (Skin Conductance Response) due to a
temporary increases of sympathetic outflow.

Results: Clozapine caused a significant reduction of heart rate
variability (e.g. mean TP vs. 54.9 in the clozapin treated patients) and an impairment of
dudomotor reaction (mean SCR: 0.5 us) as compared to healthy
controls (mean: 4. I s).

Conclusion: Under treatment with clozapine clinical relevant
effects on autonomic functions may appear. These autonomic dys-
function can be objectified by measurements of HRV, VC and SCR,
indicating effects of clozapine on cholinergic and norepinephrine-
gic autonomic functions. Long-term studies are needed to assess
the clinical implications (e.g. prediction of treatment response) of
these findings.

BEHAVIOURAL GENETICS OF COGNITIVE
DISTURBANCES IN SCHIZOPHRENIA
M.V. Alifimova*, L.G. Uvarova, V.I. Trubnikov. Department of
Preventive Genetics, Mental Health Research Centre RAMN, d.2
korp.2 Zagorodnoe shoOse. 113152: Moscow, Russia

The present study aimed at searching for genetically independent
domains of cognitive disturbances in schizophrenia and at the
level of predisposition to the psychosis. ICD-10 schizophrenics and
schizoaffectives (n = 83) and their healthy first-degree relatives (n
= 127) completed a battery of tests designed to measure attention,
memory, thinking, verbal and communication abilities. Test scores
were standardized based on the means and standard deviations
of 110 normals and subjected to a principal component analy-
sis. Factors obtained were further investigated with behavioural
genetics methods in 56 families of schizophrenics. In addition,
we examined correlations of these factors with EEG-measures in
subsamples of 44 patients and 66 relatives. In the patients, the
analysis revealed four factors labelled the mental activity (with
heritability (Ga) of 42%), executive working memory (Ga = 12%),
short-term memory for words and stories (Ga = 61%), and verbal
fluency (Ga = 6%). The factors in the group of relatives were short-
term memory for words (Ga = 52%), semantic organization (Ga
= 43%), executive working memory (Ga < 20%), communication
functioning (Ga = 34%). The cognitive factors had specific and
shared EEG-correlates. In the patients, the shared EEG-correlates
were EEG-measures of left temporal regions. In the relatives, these
were EEG-measures of right anterior and bilateral posterior regions.
Genetic correlations between the factors were low. These results
suggest that: 1) peculiarities of verbal short-term memory, semantic
organization and communication functioning may be genetically
independent cognitive indicators of liability to schizophrenia; 2) mental activity, executive working memory and verbal fluency
deficits are rather cognitive indicators of different pathophysiological
factors of the overt illness.

MULTICENTER DOUBLE BIND RANDOMIZED
OARULKEL-GROUP CLINICAL TRIAL OF
EFFECTIVENESS OF THE COMBINAION CLOMIPRAMINE
PLUS LITHIUM CARBONATE VERSUS CLOMIPRAMINE
PLUS PLACEBO IN THE TREATMENT OF UNIPOLAR
DEPRESSION
Department of Psychiatry. SHU PR LOO PR OLIE. 7 Rue Cahan-
nis. 75014 Paris, France

Introduction: The primary objective of this study was to compare
the effectiveness of a combination of clomipramine + lithium
(C+L) with that of clomipramine + placebo (C+P) in patients with
unipolar major depression, during the first 11 days of treatment.
Secondary objectives were the assessment of effectiveness after 6
weeks and assessment of the safety of the combination and lithium
carbonate.

Methodology: C+L and C+P were compared for 6 weeks in a
multicenter randomized trial of 149 patients hospitalized (DSMIV
diagnostic of major depression). Effectiveness was evaluated using
the standard MADRS and CGI scales.
Result: Analysis of the population showed: Comparison of mean MADRS scores (C+L: 25.1 versus C+P: 27.8) showed a significant difference in the C+L group on days 4 and 7 (C+L: 18.6 versus C+P: 21.3) and approaching significance on day 11 (C+L: 18.6 versus C+P: 17.2). On day 7, the number of patients in total remission was three-fold higher in the C+L group than in the C+L group (15% versus 4% p < 0.05) and two fold day 11 (29% versus 14% p < 0.05). After 6 weeks of treatment, MADRS score in the C+L group was 2.5 points lower than the C+P group (C+L: 7.6 [6.6] versus 10.1 [8.3; p = 0.09]). Safety based upon clinical and laboratory parameters was satisfactory in both groups.

Conclusion: This double-blind study seems confirmed that lithium potentiates antidepressant treatment in unipolar non refractory patients with severe major depression in the first days of treatment.

THE NETWORKING MODEL IN THE PREVENTION OF CHILD ABUSE AND NEGLECT

M. Pejovic Milovanovic*, O. Vidovic, V. Ispanovic Radojkovic, T. Mincic. Institute for Mental Health, Palmiticeva 37, 11000 Belgrade, Yugoslavia

Objective: The purpose of the following presentation would be to present the networking model of prevention and treatment strategies in working with child abuse and neglect at Belgrade, Yugoslavia. The networking model has been started in 1999 and is still in developing.

Method: According to the System of the child abuse prevention, Seattle WA-USA, the networking model consists of several levels and different organizations which all work in cooperation: Institute for mental health (where the team for prevention and treatment of child abuse and neglect has been settled), centers for social work in the different region of the capital and other organizations (such as courts).

Results: The aim of the networking model is to rise up the level of conscious in our surrounding and to promote recognition of child abuse and neglect, then to prevent further maltreatment in families and to promote early detection of existing abuse. The networking model is still in process of the organization, but the first positive results are already evident.

Conclusion: The focus of our networking model in the future would be on prevention strategies as well as on early detection and treatment procedure. The aim would be to improve programs and policies that focus on prevention-to teach parents parental skills, to prevent unplanned pregnancies, to work on family preservation and to deal with three "P"- poverty, population and pollution.

FIRST EPISODE OF SCHIZOPHRENIA – EFFICACY OF OLANZAPINE AS FIRST CHOICE NEUROLEPTIC

D. Prelipceanu*, R. Mihairescu, C. Andreescu. "Prof. Dr. Al. Obregia" Clinical Hospital of Psychiatry, 10-12 Becerei Str. Bucharest, Romania

Objectives: a) Evaluation of olanzapine’s efficacy in first episode of schizophrenia (ICD 10), based on the evolution of BPRS and CGI (severities and improvement) scores; b) evaluations of olanzapine’s safety based on CGI (adverse reaction severity) and AIMS scores.

Method: Open study of 58 patient (40 males, 18 females) treated with 10, 15 or 20 mg of olanzapine per day for a period of 30 days. Inclusion criteria: these patients were diagnosed with schizophrenia (ICD-10), being selected from a larger lot of 71 patients hospitalized with non-organic acute psychotic disorder as initial diagnosis; BPRS score of minimum 18 and CGI severity score of minimum 4. Instruments: BPRS, CGI, AIMS.

Conclusions: 1) The efficacy of olanzapine was demonstrated by a significant (p < 0.001) reduction of total BPRS score after 30 days of treatment; 2) the safety of the treatment was demonstrated by the significant (p < 0.001) reduction of the CGI (adverse reactions) score and by the evolution of the AIMS score (media per item for the final AIMS score = 1.058).

PSYCHOSOCIAL CORRELATES OF ENDOCRINE DISEASE: THE INTEGRATION OF DIFFERENT CRITERIA

N. Sonino*, C. Ruini, F. Ottolini, C. Navarrini, G.A. Favaz. 1Division of Endocrinology, Department of Medical and Surgical Sciences. University of Padua, Padua; 2Department of Psychology, University of Bologna, Bologna, Italy

Endocrine disorders have long been regarded as frequently associated with psychological distress. The aim of this study was to apply DSM-IV criteria for psychiatric disorders and 3 of the Diagnostic Criteria for Psychosomatic Research (DCPR) to a consecutive series of 74 patients admitted to an endocrine division. The DCPR have been proposed by an international group of investigators and are aimed to translate psychosocial variables that were derived from psychosomatic research into operational tools. Three of the 12 sets of criteria (irritable mood, persistent somatization, and demoralization) were used in this study. Forty-one patients (55%) were found to suffer from a DSM disorder, whereas at least one DCPR diagnosis was found in 53 patients (72%). Half of the patients who had no psychiatric diagnosis could be identified as presenting with a DCPR syndrome. The joint use of DSM and DCPR criteria was found to improve the identification of psychological distress in endocrine patients.

QUALITY OF LIFE PROFILE IN PATIENTS WITH SUICIDAL ACTIVITY (IDEATION OR ATTEMPT)

C. Fernández, P.A. Sáiz*, J.C. González, M.P. González, Y. Rams, M. Bousoño. Department of Psychiatry, University of Oviedo Faculty of Medicine, 6: Julián Clavería, 3 floor, 33006 Oviedo, Asturias, Spain

Objective: To determine differences in quality of life (QoL) profile among patients with suicidal attempt -SA- or ideation -SI- and, other psychiatric inpatients -controls-.

Subjects and Method: 126 inpatients [46 SA, 37 SI, and 43 other psychiatric illness] from the Psychiatric Unit of the Hospital de Jove (Asturias - Northern Spain) were interviewed using the SF-36, during 1997-98.

Results: Mean age: SA: 39.1; SI: 42.5; control: 39.4. Males-SA: 51.0%; SI: 47.4%; control: 57.4% (no sociodemographic or family psychiatric suicidal history differences). Patients with suicidal activity (attempt + ideation) vs controls (data showed if p < .05) - physical functioning (PF): 82.6 vs 89.9; general health (GH): 45.1 vs 66.4; vitality (V): 35.7 vs 60.3; social functioning: 45.4 vs 73.8 (SF); role emotional (RE): 27.2 vs 55.7; and mental health (MH): 35.3 vs 57.7. Patients with SA and SI only differentiate in SF (SA: 38.0, SI: 54.9; p = .034). Males -suicidal activity vs controls- (data showed if p < .05). Physical functioning (PF): 44.5 vs 65.6; V: 40.2 vs 62.1; SF: 42.7 vs 76.0; and MH: 40.5 vs 58. Females -suicidal activity vs controls- (data showed if p < .05). GH: 45.7 vs 67.8, V: 31.1 vs 57.6; SF: 48.2 vs 70.6; RE: 10.6 vs 34.9; and MH: 30.0 vs 51.5.
