Abstract

Acanthocephalans of the order Polymorphida mainly parasitic in birds and mammals, are of veterinary, medical and economic importance. However, the evolutionary relationships of its 3 families (Centrorhynchidae, Polymorphidae and Plagiorhynchidae) remain under debate. Additionally, some species of Polymorphida (i.e. *Bolbosoma* spp. and *Corynosoma* spp.) are recognized as zoonotic parasites, associated with human acanthocephaliasis, but the mitochondrial genomes for representatives of *Bolbosoma* and *Corynosoma* have not been reported so far. In the present study, the complete mitochondrial genomes *B. nipponicum* and *C. villosum* (Acanthocephala: Polymorphidae) are reported for the first time, which are 14 296 and 14 241 bp in length, respectively, and both contain 36 genes [including 12 PCGs, 22 tRNA genes and 2 rRNA genes] and 2 non-coding regions (*NCR1* and *NCR2*). The gene arrangement of some tRNAs in the mitogenomes of *B. nipponicum* and *C. villosum* differs from that found in all other acanthocephalans, except *Polymorphus minutus*. Phylogenetic results based on concatenated amino acid (AA) sequences of the 12 protein-coding genes (PCGs) strongly supported that the family Polymorphidae is a sister to the Centrorhynchidae rather than the Plagiorhynchidae, and also confirmed the sister relationship of the genera *Bolbosoma* and *Corynosoma* in the Polymorphidae based on the mitogenomic data for the first time. Our present findings further clarified the phylogenetic relationships of the 3 families Plagiorhynchidae, Centrorhynchidae and Polymorphidae, enriched the mitogenome data of the phylum Acanthocephala (especially the order Polymorphida), and provided the resource of genetic data for diagnosing these 2 pathogenic parasites of human acanthocephaliasis.

Introduction

Acanthocephalans (commonly named as spiny- or thorny-headed worms) are an important group of obligate endoparasites occurring in the alimentary track of all major vertebrate groups (Petrochenko and Skrjabin, 1956; Yamaguti, 1963; Nickol, 1985; Naidu, 2012; Amin, 2013), which are of veterinary, medical and economic importance in domestic animals, wildlife and humans (Petrochenko and Skrjabin, 1956; Moore *et al.*, 1969; Nickol, 1985). Some acanthocephalan species of the genera *Macracanthorhynchus* Travassos, 1917, *Moniliformis* Travassos, 1915, *Corynosoma* Lühe, 1904, and *Bolbosoma* Porta, 1908, rarely *Pseudoacanthocephalus* Petrochenko, 1956 and *Acanthocephalus* Koelreuther, 1771, are recognized as zoonotic parasites associated with human acanthocephaliasis (Skrinnik *et al.*, 1958; Schmidt, 1971; Leng *et al.*, 1983; Miyazaki, 1991; Berenji *et al.*, 2007; Fujita *et al.*, 2016).

The present knowledge regarding the basic molecular phylogenetic framework of the phylum Acanthocephala Rudolphi, 1808 remains far from complete. Previous studies indicated that the mitochondrial genomes play important roles in the phylogenetics, population genetics and species identification of acanthocephalans (Gazi *et al.*, 2016; Song *et al.*, 2016; Pan and Jiang, 2018; Muhammad *et al.*, 2019a, 2019b, 2020a, 2020b, 2020c; Dai *et al.*, 2022; Gao *et al.*, 2022). However, the mitogenomes have been sequenced for only 29 acanthocephalian species, which belonged to 13 families in 6 orders. To date, there are approximately 98% of nominal species and 87% of genera in Acanthocephala with their mitogenomes unavailable

so far, which somewhat hinder understanding the mitogenomic evolution and phylogenetics in Acanthocephala.

The order Polymorphida Petrochenko, 1956 currently includes 3 families Plagiorhynchidae Golvan, 1960, Centrorhynchidae Van Cleave, 1916 and Polymorphidae Meyer, 1931 (Amin, 2013). Until now, the evolutionary relationships of the 3 families remain under debate. Some previous molecular analyses considered the Plagiorhynchidae and Polymorphidae to have an affinity (García-Varela *et al.*, 2013; Gazi *et al.*, 2015; Muhammad *et al.*, 2020a, 2020b, 2020c); however, other studies supported the Polymorphidae and Centrorhynchidae have closer relationship than the Plagiorhynchidae (Gazi *et al.*, 2016; Song *et al.*, 2019; Muhammad *et al.*, 2019a, 2019b; Dai *et al.*, 2022; Gao *et al.*, 2022; Zhao *et al.*, 2023).

In Polymorphida, the Polymorphidae is the largest family and contains 12 genera, namely *Andracantha* Schmidt, 1975, *Ardeirhynchus* Dimitrova and Georgiev, 1994, *Arhythmorrhynchus* Lühe, 1911, *Bolbosoma*, *Corynosoma*, *Diplospinifer* Fukui, 1929, *Filicollis* Lühe, 1911, *Ibirhynchus* García-Varela, de León, Aznar et Nadler, 2011, *Polymorphus* Lühe, 1911, *Profilicollis* Meyer, 1931, *Pseudocorynosoma* Aznar, de León et Raga, 2006, and *Southwellina* Witenberg, 1932, with over 120 species reported from marine mammals, fish-eating marine birds and waterfowls worldwide (Deliamure, 1968; Schmidt, 1975; Dimitrova and Georgiev, 1994; Aznar *et al.*, 2006; García-Varela *et al.*, 2011, 2013; Amin, 2013). Several species of *Bolbosoma* and *Corynosoma*, for example, *Bolbosoma* cf. *capitatum*, *Bolbosoma* sp., *Corynosoma villosum* Van Cleave, 1953, *C. strumosum* (Rudolphi, 1802), *C. validum* Van Cleave, 1953 and *Corynosoma* sp. are recognized as parasites associated with human acanthocephalasis (Beaver *et al.*, 1983; Tada *et al.*, 1983; Ishikura *et al.*, 1996; Mori *et al.*, 1998; Hino *et al.*, 2002; Isoda *et al.*, 2006; Arizono *et al.*, 2012; Fujita *et al.*, 2016; Takahashi *et al.*, 2016; Kaito *et al.*, 2019; Santoro *et al.*, 2021). Despite their significance, the mitochondrial genomes for representatives of *Bolbosoma* and *Corynosoma* have not been reported.

In the present study, the complete mitochondrial genomes of *Bolbosoma nipponicum* Yamaguti, 1939 and *C. villosum* (Acanthocephala: Polymorphidae) are sequenced and annotated for the first time, based on specimens collected from the northern fur seal *Callorhinus ursinus* (Linnaeus) (Mammalia: Carnivora) and the Pacific halibut *Hippoglossus stenolepis* (Schmidt) (Pleuronectiformes: Pleuronectidae) in Alaska, USA, which also represented the first mitogenome from the genera *Bolbosoma* and *Corynosoma* (Polymorphida: Echinorhynchidae). Additionally, in order to further clarify the evolutionary relationships of the 3 families Plagiorhynchidae, Centrorhynchidae and Polymorphidae in the order Polymorphida, phylogenetic analyses based on concatenated amino acid (AA) sequences of the 12 protein-coding genes (PCGs) of all available acanthocephalian mitogenomes were performed using Bayesian inference (BI) and maximum likelihood (ML), respectively.

Materials and methods

Species identification

The acanthocephalan specimens of *B. nipponicum* and *C. villosum* were collected from the intestine of subadult northern fur seals *Callorhinus ursinus* (Linnaeus) (Mammalia: Carnivora) and *Hippoglossus stenolepis* (Schmidt) (Pleuronectiformes: Pleuronectidae) in St. Paul Island, Alaska, USA, fixed and stored in 70% ethanol. The specimens were identified as *B. nipponicum* and *C. villosum* based on morphological features according to previous studies (Van Cleave, 1953; Margolis, 1956; Ru *et al.*, 2022). Voucher specimens were deposited in the College of

Life Sciences, Hebei Normal University, Hebei Province, China (*B. nipponicum*: HBNU-A-2022M002L; *C. villosum*: HBNU-A-2022F003L).

Molecular procedures

The total genomic DNA of each individual of *B. nipponicum* and *C. villosum* was extracted using the Magnetic Universal Genomic DNA Kit (DP705) (Tiangen Biotech, Beijing, China) according to the manufacturer's instructions: (1) cut the sample tissue into small pieces, add 300 µL tissue digestives GHA and 20 µL Proteinase K, and grind the tissue thoroughly; (2) transfer the above-treated sample solution of 300 µL into a new 1.5 mL centrifuge tube; (3) add 300 µL lysate GHL and 300 µL isopropyl alcohol, shake and mix well; (4) add 15 µL magnetic bead suspension GH, shake and mix for 1 min, stand for 9 min in total, shake and mix for 1 min each 3 mins; (5) the centrifuge tube was placed on the magnetic rack and stood for 30 s. After the magnetic bead was completely absorbed, the liquid was carefully absorbed, and the DNA solution was transferred to the new centrifuge tube. The genomic DNA sample was fragmented by sonication to a size of 350 bp in preparation for genomic library.

A total of 20 GB of gene library data for each sample of *B. nipponicum* and *C. villosum* were yielded using the Pair-End 150 sequencing method on the Illumina NovaSeq 6000 platform by Novogene (Tianjin, China). Program GetOrganelle v1.7.2a (Jin et al., 2020) was employed to reconstruct the mitochondrial genomes of these acanthocephalans. The locations of PCGs, transfer RNA (tRNA), and ribosomal RNA (rRNA) in the generated mitochondrial genomes were roughly annotated using MitoZ v2.4 (Meng et al., 2019) and web-servers MITOS (<http://mitos.bioinf.uni-leipzig.de/index.py>). All PCGs were confirmed manually using the ORF finder (<https://www.ncbi.nlm.nih.gov/orffinder/>) based on the invertebrate mitochondrial genetic code. Transfer RNA genes were additionally identified using BLAST-based on a database of the existing tRNA sequences of Acanthocephala. The secondary structures of tRNAs were predicted by the ViennaRNA module (Gruber et al., 2015) and then manually corrected building on MitoS2 (Bernt et al., 2007) and RNAstructure v6.3 (Reuter and Mathews, 2010). The CGView online server V1.0

(http://stothard.afns.ualberta.ca/cgview_server/) was used to generate the circular genomic maps. The base composition, amino acid usage and relative synonymous codon usage (RSCU) were calculated by Python script (details see the Supplementary material), which refers to codon adaptation index (Cock et al., 2009). Strand asymmetry was calculated using the formulae: AT-skew = (A - T)/(A + T); GC-skew = (G - C)/(G + C). The complete mitochondrial genomes of *B. nipponicum* and *C. villosum* obtained herein were deposited in the GenBank database (<http://www.ncbi.nlm.nih.gov>, under the accession numbers *Corynosoma villosum*: OR468095, *Bolbosoma nipponicum*: OR468096).

Phylogenetic analyses

Phylogenetic analyses were conducted based on concatenated amino acid (AA) sequences of the 12 PCGs using BI and ML, respectively. Two species of Bdelloidea, *Rotaria rotatoria* (NC013568.1) and *Philodina citrina* (FR856884.1) were chosen as the out-group. The in-group included the newly sequenced *B. nipponicum* and *C. villosum* and the other 29 species of acanthocephalans with mitogenomic data. Detailed information on representatives included in the present phylogeny was provided in Table 1. For phylogenetic analyses, PhyloSuite was used to collect all mitogenomic sequences from GenBank files, standardize annotation and extract mitogenomic data (Zhang et al., 2020). The extracted amino acid sequences of all 12 PCGs were aligned in MAFFT v7.313 under iterative refinement method of E-INS-I (Katoh and Standley, 2013). The AAs dataset was concatenated into a single alignment by PhyloSuite, respectively. Substitution models were compared and selected according to the Bayesian Information Criterion (BIC) by using ModelFinder (Kalyaanamoorthy et al., 2017). The VT + F + I + G4 was identified as the optimal amino acid substitution model for both partitions (partition1: *cox1*, *cox2*, *nad1*; partition2: all other genes). Bayesian Information Criterion analysis settings were lser nst = 6, rates = invgamma, mcmc ngen = 5 000 000, printfreq = 1000, samplefreq = 100, nchains = 4, nruns = 2. The analysis continued until the average standard deviation of split frequencies was lower than 0.01. The first 25% of trees were

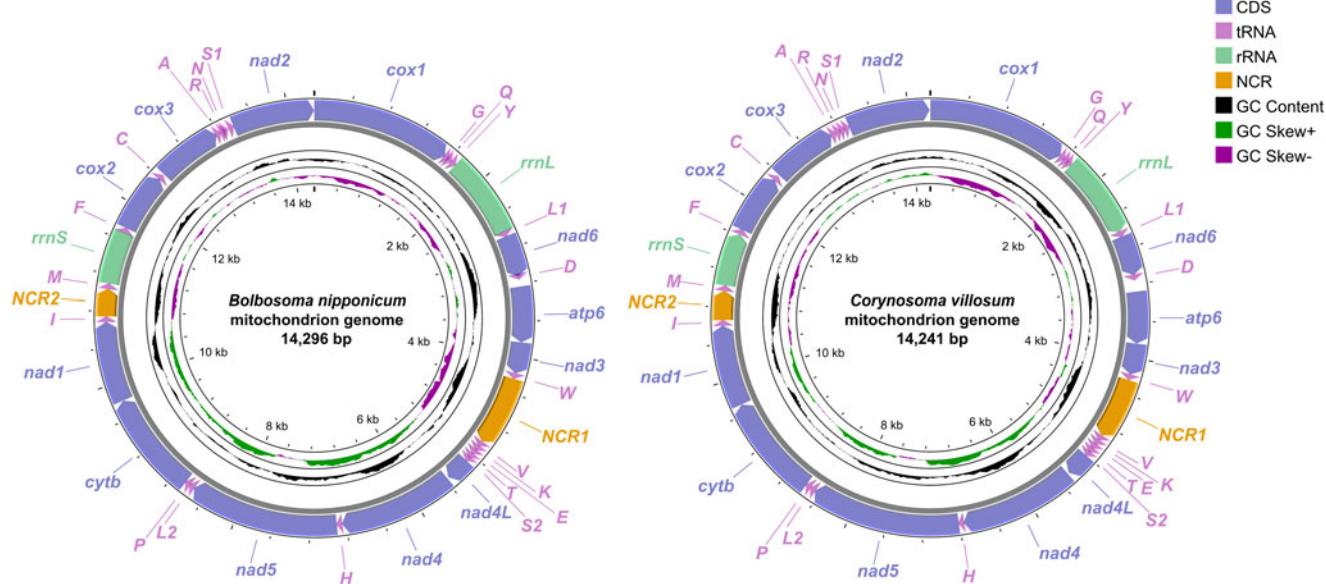

Figure 1. Gene maps of the mitochondrial genomes of *Bolbosoma nipponicum* and *Corynosoma villosum*. All genes are transcribed in the clockwise direction on the same strand, and 22 tRNA genes are designated by the 1-letter code with numbers differentiating each of the 2 tRNAs serine and leucine. The outermost circle shows the GC content and the innermost circle shows the GC skew.

treated as ‘burn-in’. For ML analysis, 1000 bootstrap replicates were used to calculate the bootstrap of the program in IQTREE v2.1.2, keep the default values for other parameters (Golombek *et al.*, 2015; Minh *et al.*, 2020). The iTOL v6.1.1 was used to visualize the phylogeny and architecture using files generated by PhyloSuite (Letunic and Bork, 2021).

Results

General characterization of the complete mitogenomes of *B. nipponicum* and *C. villosum*

Gene content and organization of mitogenomes

The complete mitochondrial genomes of *B. nipponicum* and *C. villosum* are 14 296 and 14 241 bp in length, respectively, and both contain 36 genes, including 12 PCGs (missing *atp8*) (*cox1–3*, *cytb*, *nad1–6*, *nad4L* and *atp6*), 22 tRNA genes and 2 rRNA genes (*rrnL* and *rrnS*) (Fig. 1, Table 2). All genes are transcribed from the same strand. Two non-coding regions (NCR1 and NCR2), are present in the same positions in the mitogenomes of *B. nipponicum* and *C. villosum* (NCR1 is 776 bp in *B. nipponicum* vs 676 bp in *C. villosum*, both located between *trnW* and *trnV*; NCR2 is 301 bp in *B. nipponicum* vs 318 bp in *C. villosum*, both between *trnI* and *trnM*) (Fig. 1; Table 2). The overall A + T contents in the mitogenomes of *B. nipponicum* and *C. villosum* are 60.88% and 60.99%, respectively (Table 3), both displaying strong A + T bias.

Protein-coding genes and codon usage

The 12 PCGs of the mitogenomes of *B. nipponicum* and *C. villosum* are 10 468 bp and 10 389 bp in total length (excluding termination codons), and ranged from 270 bp (*nad4L*) to 1,647 bp (*nad5*) in size (Table 2). Among the 12 PCGs of *B. nipponicum*, 8 genes (*cox2*, *cox3*, *cytb*, *nad2*, *nad3*, *nad4L*, *nad5* and *nad6*) used GTG as the start codon, whereas 2 genes (*nad1* and *nad4*) used ATG. ATT and TTG were used by the *atp6* and *cox1* genes, respectively. TAG was the most commonly used termination codon for 6 genes (*atp6*, *cox1*, *nad1*, *nad2*, *nad5* and *nad6*); 4 genes (*cox2*, *cox3*, *cytb* and *nad4L*) used TAA. The incomplete termination codon T was inferred for the *nad3* and *nad4* genes (Table 2).

Among the 12 PCGs of *C. villosum*, 9 genes (*cox1*, *cox2*, *cox3*, *cytb*, *nad1*, *nad2*, *nad4L*, *nad5* and *nad6*) used GTG as the start codon, whereas 3 genes (*atp6*, *nad3* and *nad4*) used ATG. TAA was the most commonly used termination codon for 6 genes (*atp6*, *cox1*, *cox2*, *cox3*, *nad2* and *nad4L*); 3 genes (*cytb*, *nad1* and *nad5*) used TAG. The incomplete termination codon T was inferred for the *nad3*, *nad4* and *nad6* genes (Table 2). RSCU is summarized in Fig. 2.

Transfer and ribosomal RNAs

In the mitogenomes of *B. nipponicum* and *C. villosum*, 22 tRNAs are identified with lengths ranging from 50 to 61 bp in *B. nipponicum*, and from 52 to 64 bp in *C. villosum* (Fig. 1, Table 2). Their anticodon secondary structures are provided (Figs 3, 4). In the 22 tRNAs of *B. nipponicum* and *C. villosum*, 5 tRNAs (*trnR*, *trnN*, *trnF*, *trnW* and *trnV*) were predicted to be folded into typical cloverleaf secondary structure, 2 tRNAs (*trnQ* and *trnS1*) lacked dihydrouridine (DHU) arm, the remaining 15 tRNAs lacked TΨC arm (Figs 3, 4, Table 2).

Two rRNAs (*rrnL* and *rrnS*) were identified in the mitogenomes of *B. nipponicum* and *C. villosum* (*rrnL* is 913 bp in *B. nipponicum* vs 914 bp in *C. villosum*, both located between *trnY* and

Bolbosoma nipponicum and *Corynosoma villosum* in the present study are indicated in bold.

trnL1; *rrnS* is 585 bp in *B. nipponicum* vs 584 bp in *C. villosum*, both located between *trnM* and *trnF* (Fig. 1, Table 2).

Gene order

The arrangements of the 36 genes in the mitogenomes of *B. nipponicum* and *C. villosum* are identical, both in the following order: *cox1*, *trnG*, *trnQ*, *trnY*, *rrnL*, *trnL1*, *nad6*, *trnD*, *atp6*, *nad3*, *trnW*, *trnV*, *trnK*, *trnE*, *trnT*, *trnS2*, *nad4L*, *nad4*, *trnH*, *nad5*, *trnL2*, *trnP*, *cytb*, *nad1*, *trnI*, *trnM*, *rrnS*, *trnF*, *cox2*, *trnC*, *cox3*, *trnA*, *trnR*, *trnN*, *trnS1*, *nad2* (Fig. 5).

Phylogenetic analyses

In the present study, phylogenetic trees based on concatenated amino acid sequences of the 12 PCGs using ML and BI methods have nearly same topologies, except the supported value of some branches, which all showed that the representatives of the phylum Acanthocephala were divided into 3 large monophyletic clades (Figs 6). Clade I includes *Moniliformis* sp., *Macracanthorhynchus hirudinaceus* and *Oncicola luehei*, which represents the class Archiacanthocephala at the most basal position of the phylogenetic trees. Clade II contains the representatives of the class Eoacanthocephala (*Acanthogyrus bilaspurensis*, *A. cheni*, *Hebesoma violentum*, *Paratenensis ambiguus* and *Pallensis celatus*) and *Polyacanthorhynchus caballeroi* (belonging to the class Polyacanthocephala). Clade III is composed of the representatives

of the class Palaeacanthocephala, of which the order Echinorhynchida (including *Cavisoma magnum*, *Echinorhynchus truttae*, *Pseudoacanthocephalus bufonis*, *Brentisentis yangtzensis*, *Pomphorhynchus* spp., *Leptorhynchoides thecatus* and *Micracanthorhynchina dakusuiensis*) is a non-monophyletic group, but the order Polymorphida (including *Plagiorhynchus transversus*, *Polymorphus minutus*, *Southwellina hispida*, *Centrorhynchus* spp., *Sphaerirostris* spp., *Bolbosoma nipponicum* and *Corynosoma villosum*) is a monophyletic group. In the order Polymorphida, the family Polymorphidae is a sister to the family Centrorhynchidae. *Bolbosoma nipponicum* and *Corynosoma villosum* clustered together with strong nodal support (BPP = 1, ML-BP = 100) in all BI and ML trees.

Discussion

The order Polymorphida is a large group of Acanthocephala, containing over 370 nominal species mainly parasitic in birds and mammals, rarely in reptiles (Amin, 2013; Zhao *et al.*, 2020; Ru *et al.*, 2022). According to the traditional classification, Polymorphida was divided into 3 families (Centrorhynchidae, Polymorphidae, and Plagiorhynchidae), including 24 genera (Amin, 2013). However, only 8 species representing 5 genera with their mitochondrial genomes have been documented (Gazi *et al.*, 2015, 2016; Muhammad *et al.*, 2019*a*, 2019*b*, 2020*a*, 2020*b*; Sarwar *et al.*, 2021). In Polymorphida, the size of mitochondrial genomes of *B. nipponicum* and *C. villosum* is similar

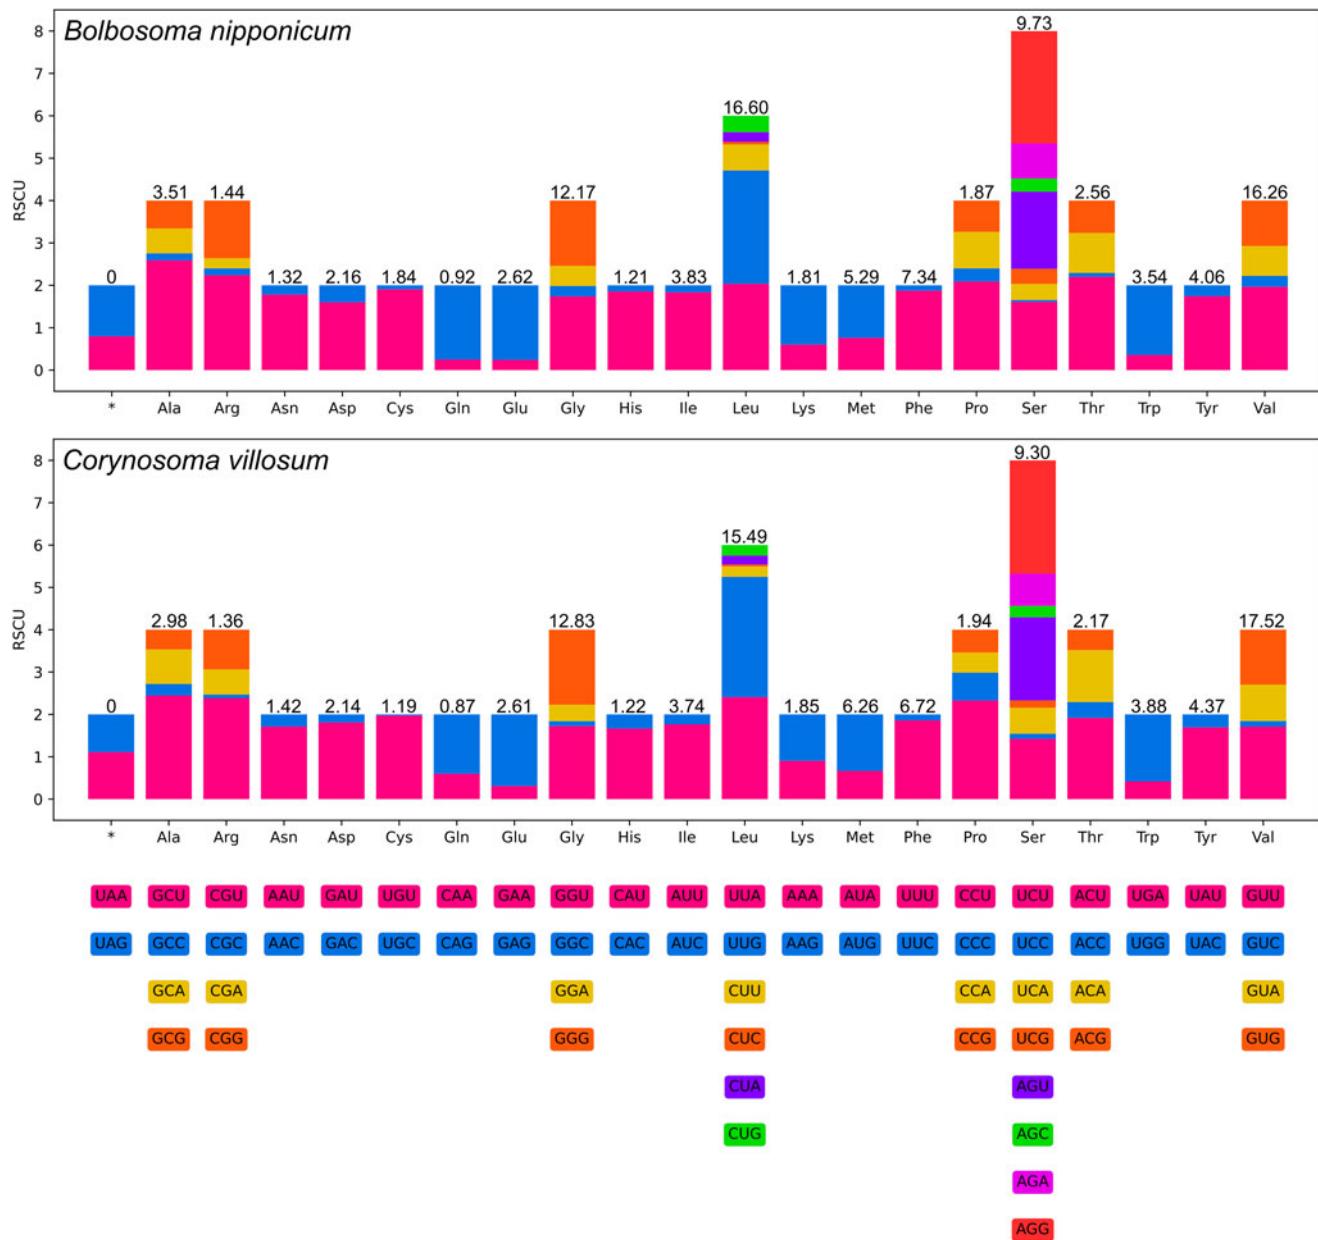

Figure 2. Relative synonymous codon usage (RSCU) of *Bolbosoma nipponicum* and *Corynosoma villosum*. Codon families (in alphabetical order) are provided below the horizontal axis. Values on the top of each bar represent amino acid usage in percentage.

to that of the polymorphid species *Polymorphus minutus* and *Southwellina hispida*; however, the overall A + T contents in the mitogenomes of *B. nipponicum* and *C. villosum* are slightly lower than that of *P. minutus* and *S. hispida* (60.88–60.99% in *B. nipponicum* and *C. villosum* vs 63.9–64.4% in the latter 2 species) (Gazi *et al.*, 2015; Sarwar *et al.*, 2021), but distinctly higher than that of centrorhynchid species (54.5–58.1%) (Muhammad *et al.*, 2019a, 2019b, 2020a, 2020b; Gazi *et al.*, 2016).

Previous studies indicated that the arrangements of the 12 PCGs and 2 rRNAs in the phylum Acanthocephala are highly conserved, while the position of tRNAs usually varied among different families, genera or species (Gazi *et al.*, 2012, 2016; Dai *et al.*, 2022; Gao *et al.*, 2022; Zhao *et al.*, 2023). In the family Polymorphidae, the arrangements of the 36 genes in the mitogenomes of *B. nipponicum* and *C. villosum* are identical to that of *P. minutus* (Sarwar *et al.*, 2021), but the positions of some tRNAs are different from that of the polymorphid species *S. hispida* (Gazi *et al.*, 2015) and all of the species of Centrorhynchidae

and Plagiorhynchidae (Muhammad *et al.*, 2019a, 2019b, 2020a, 2020b; Gazi *et al.*, 2016).

Recent mitogenomic phylogenies brought substantial changes to the traditional classification of Acanthocephala. However, phylogenetic relationships within many lineages of the class Palaeacanthocephala remain insufficiently resolved, due to large numbers of taxa (i.e. the order Heteramorphida, and the families of Illiosentidae, Isthmosacanthidae, Heteracanthocephalidae, Fesssentidae, Diplosentidae, Transvenidae, Spinulacorpidae Hypoechinorhynchidae and Gymnorhadinorhynchidae of the order Echinorhynchida) that have not been included yet. Although all of the 3 family-level taxa (Plagiorhynchidae, Centrorhynchidae and Polymorphidae) of the order Polymorphidae have been included in some previous mitogenomic phylogenetic studies, very limited genus/species-level taxa have been covered in each family. The evolutionary relationships of the 3 families in Polymorphida and its included genera of each family remain unsolved.

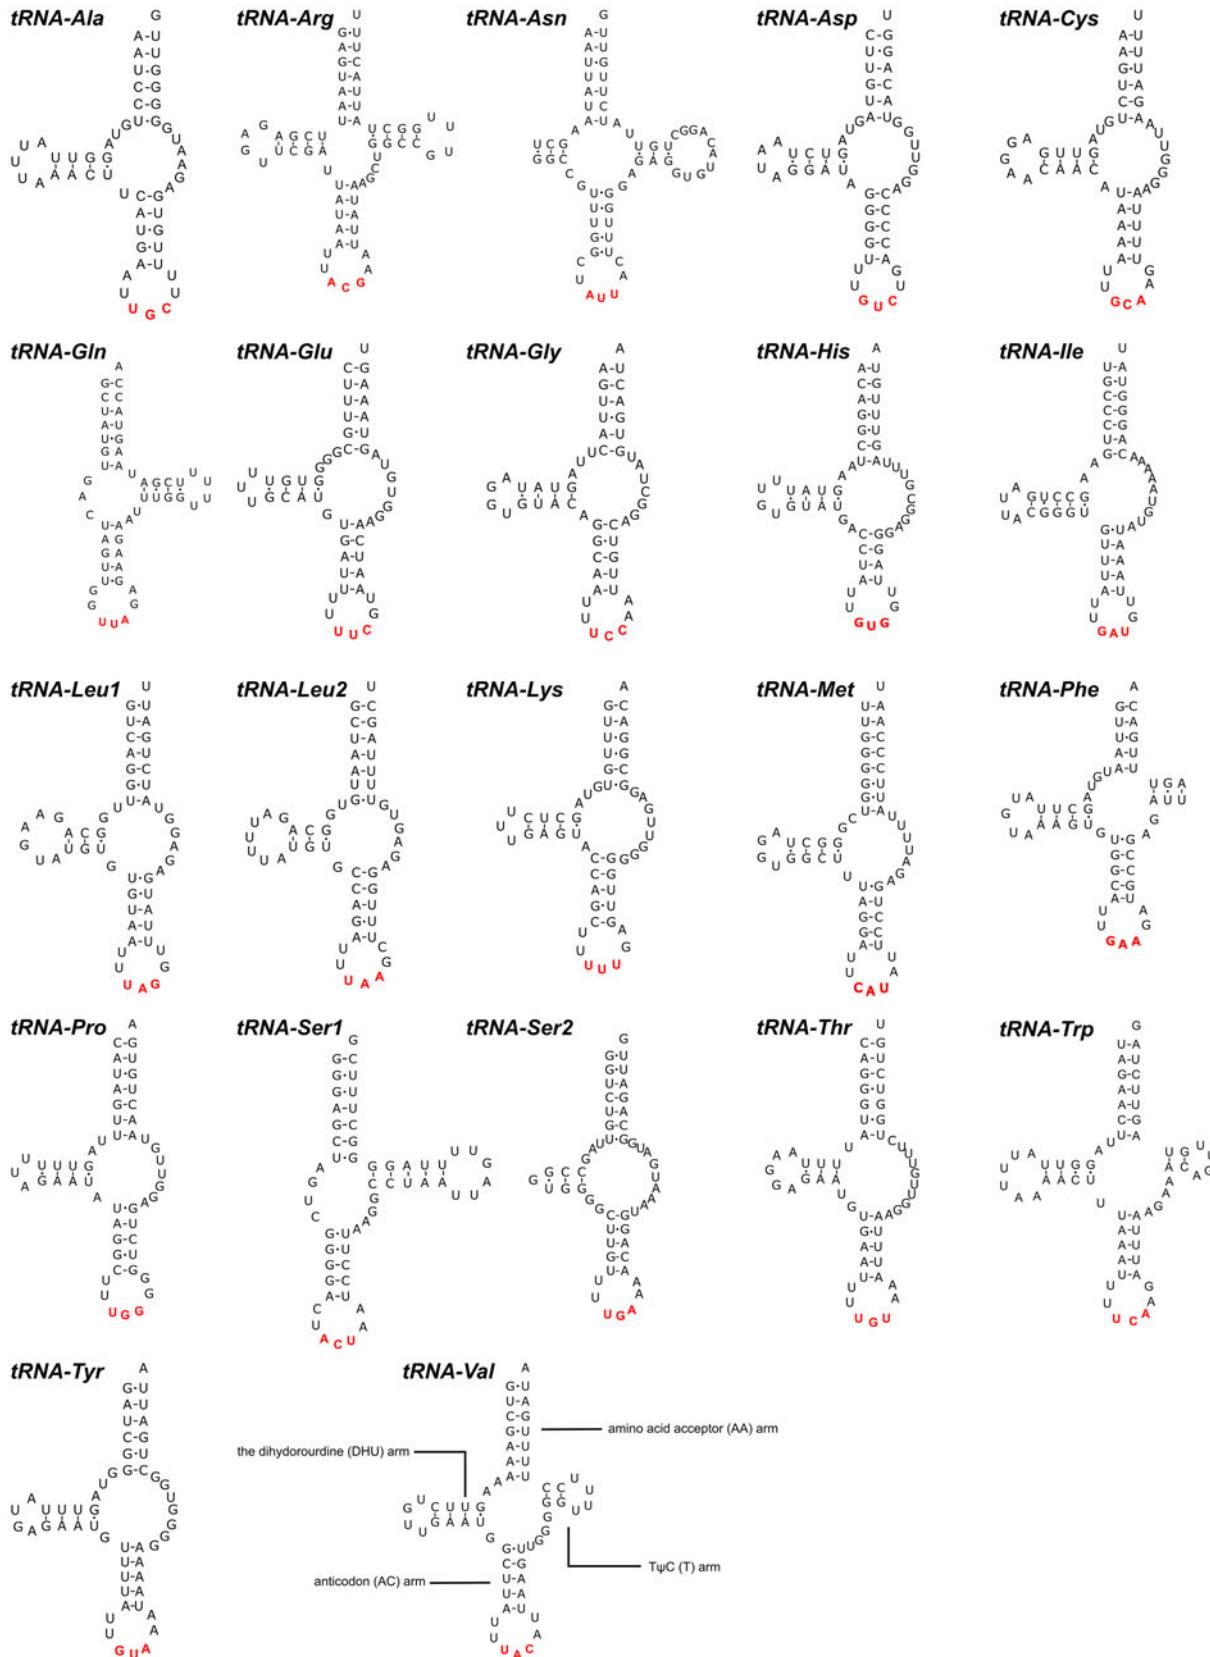

Bolbosoma nipponicum

Figure 3. The predicted secondary structures of 22 tRNAs in the mitogenome of *Bolbosoma nipponicum* (Watson-Crick bonds indicated by lines, GU bonds indicated by dots, red bases representing anticodons). The tRNAs are labelled with the abbreviations of their corresponding amino acids according to the IUPAC-IUB code.

Corynosoma villosum

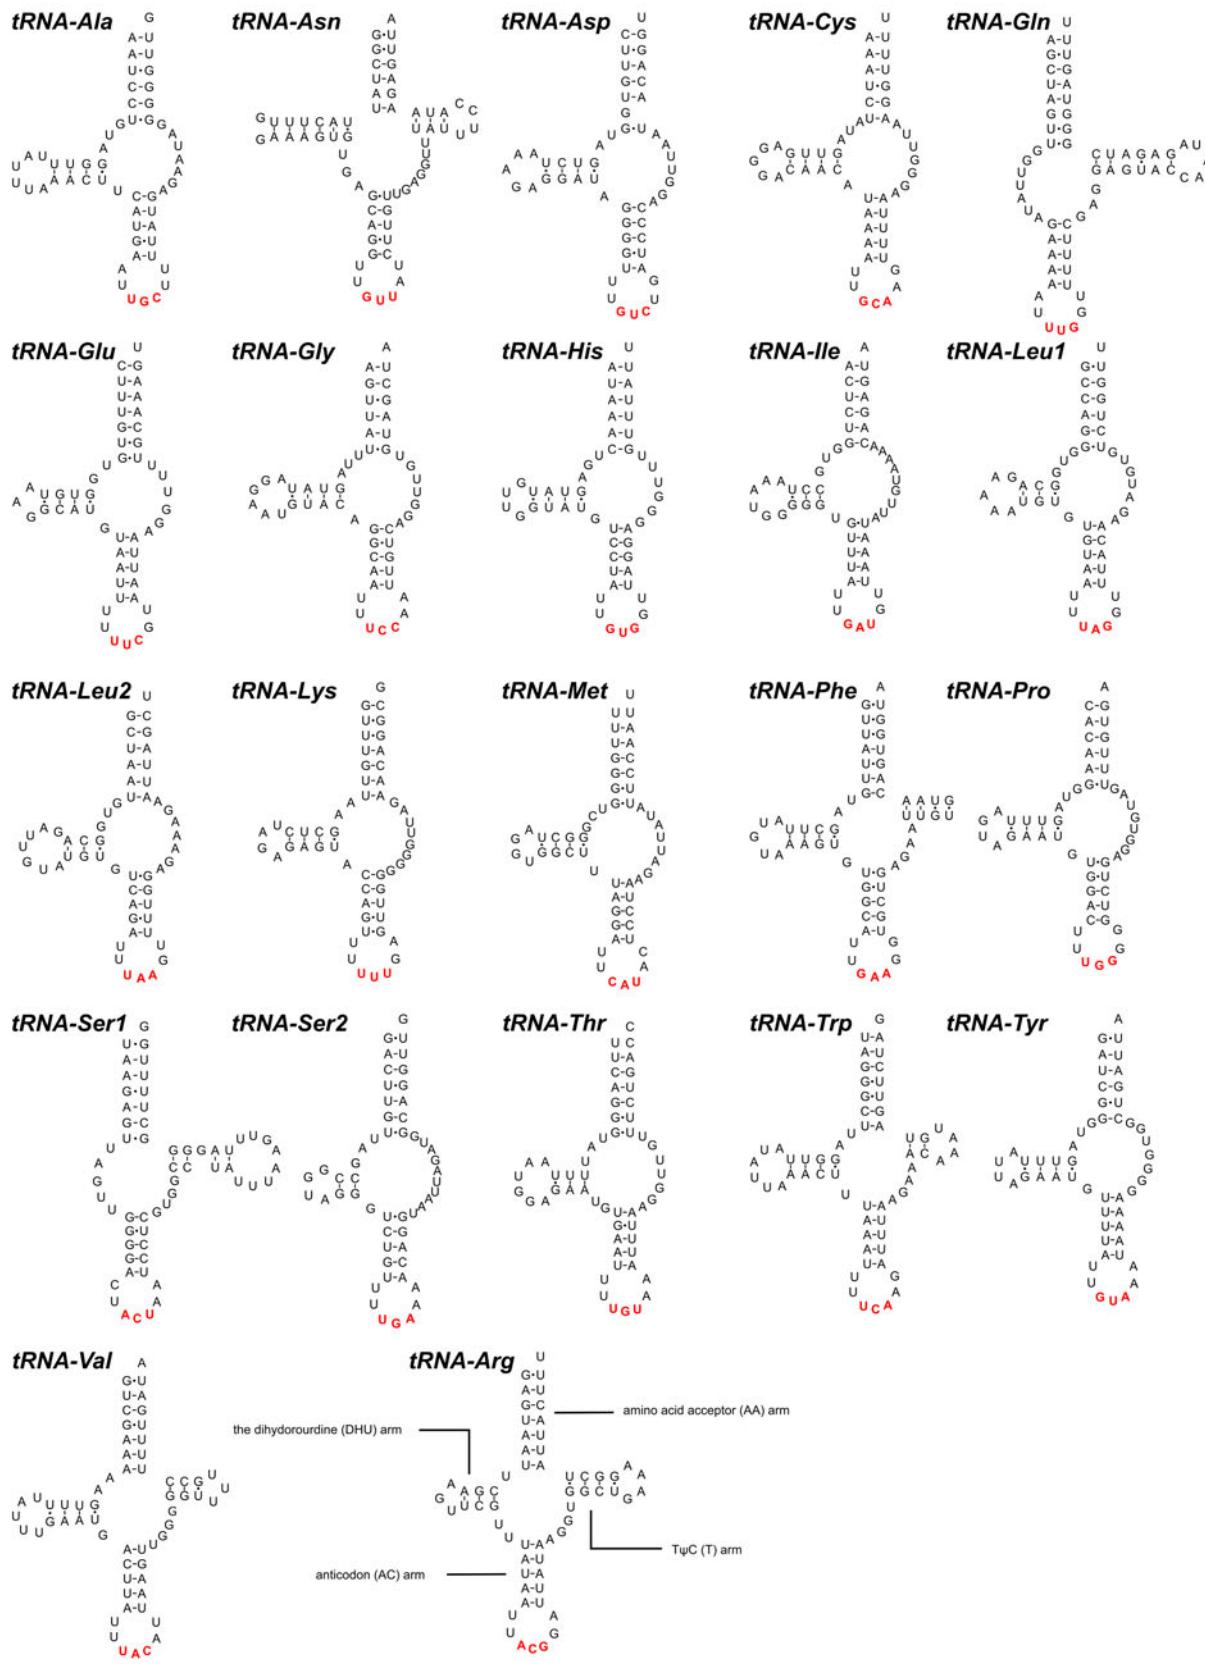

Figure 4. The predicted secondary structures of 22 tRNAs in the mitogenome of *Corynosoma villosum* (Watson-Crick bonds indicated by lines, GU bonds indicated by dots, red bases representing anticodons). The tRNAs are labelled with the abbreviations of their corresponding amino acids according to the IUPAC-IUB code.

The present mitogenomic phylogenies showed that the order Polymorphida is a monophyletic group, but rejected the monophyly of the order Echinorhynchida, in agreement with the previous studies (García-Varela and Nadler, 2006; García-Varela and

de León, 2008; Verwegen *et al.*, 2011; García-Varela *et al.*, 2013; Braicovich *et al.*, 2014). The previous molecular phylogenetic results using single or several concatenated genetic markers (i.e. 18S, 18S + 28S + cox1) (Near *et al.*, 1998; García-Varela *et al.*,

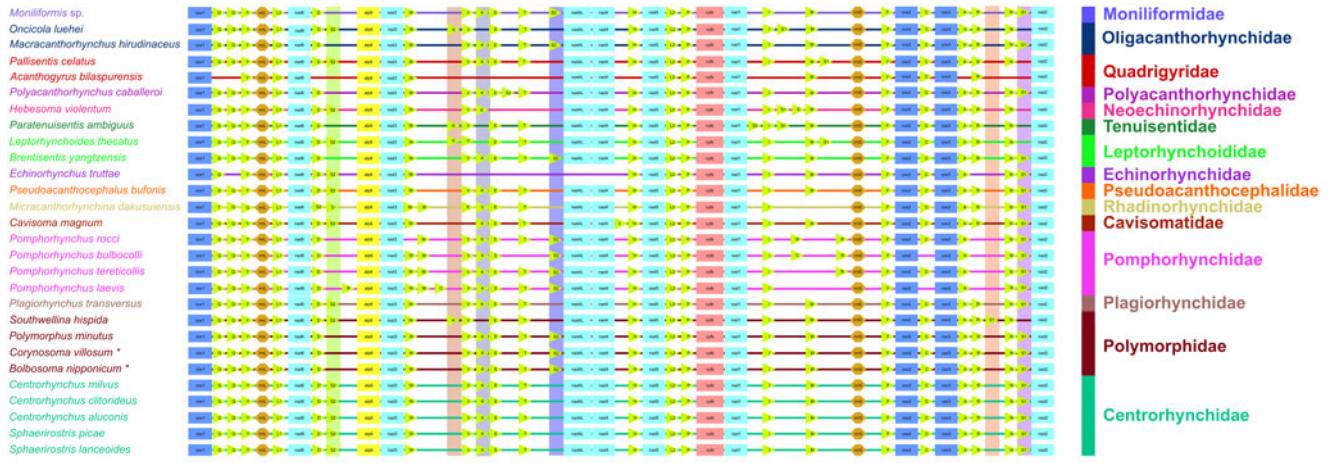

Figure 5. Comparison of the linearized mitochondrial genome arrangement for acanthocephalans species. All genes are transcribed in the same direction from left to right. The tRNAs are labelled by single-letter code for the corresponding amino acid. *Bolbosoma nipponicum* and *Corynosoma villosum* are indicated using asterisk (*).

2013) and some recent mitogenomic phylogenies (Muhammad *et al.*, 2020a, 2020b, 2020c; Sarwar *et al.*, 2021) indicated that the Plagiorhynchidae is a sister to the Polymorphidae or Centrorhynchidae. However, the present phylogenetic results strongly displayed that the Polymorphidae and Centrorhynchidae are more closely related to each other than to the Plagiorhynchidae (Gazi *et al.*, 2016; Muhammad *et al.*, 2019a, 2019b; Song *et al.*, 2019; Dai *et al.*, 2022; Gao *et al.*, 2022; Zhao *et al.*, 2023). Although Zhao *et al.* (2023) study also suggests a close affinity between the Polymorphidae and Centrorhynchidae, there are only 2 representatives of the Polymorphidae in their phylogeny, and the supported value for the close phylogenetic relationship of the Polymorphidae and Centrorhynchidae is weak.

However, the present phylogenetic study including 2 additional genus-level taxa of the Polymorphidae, showed strong support for the close affinity between the Polymorphidae and Centrorhynchidae in both ML (BS = 98) and BI (BPP = 1).

Our phylogenetic results also revealed the genus *Bolbosoma* has a sister relationship with *Corynosoma* based on the mitogenomic data for the first time, in concordance with previous studies based on single or several concatenated genetic markers (García-Varela *et al.*, 2013; Presswell *et al.*, 2018; Ru *et al.*, 2022). Moreover, the present findings further clarified the phylogenetic relationships of the 3 families Plagiorhynchidae, Centrorhynchidae and Polymorphidae, enriched the mitogenome data of the phylum Acanthocephala (especially the order

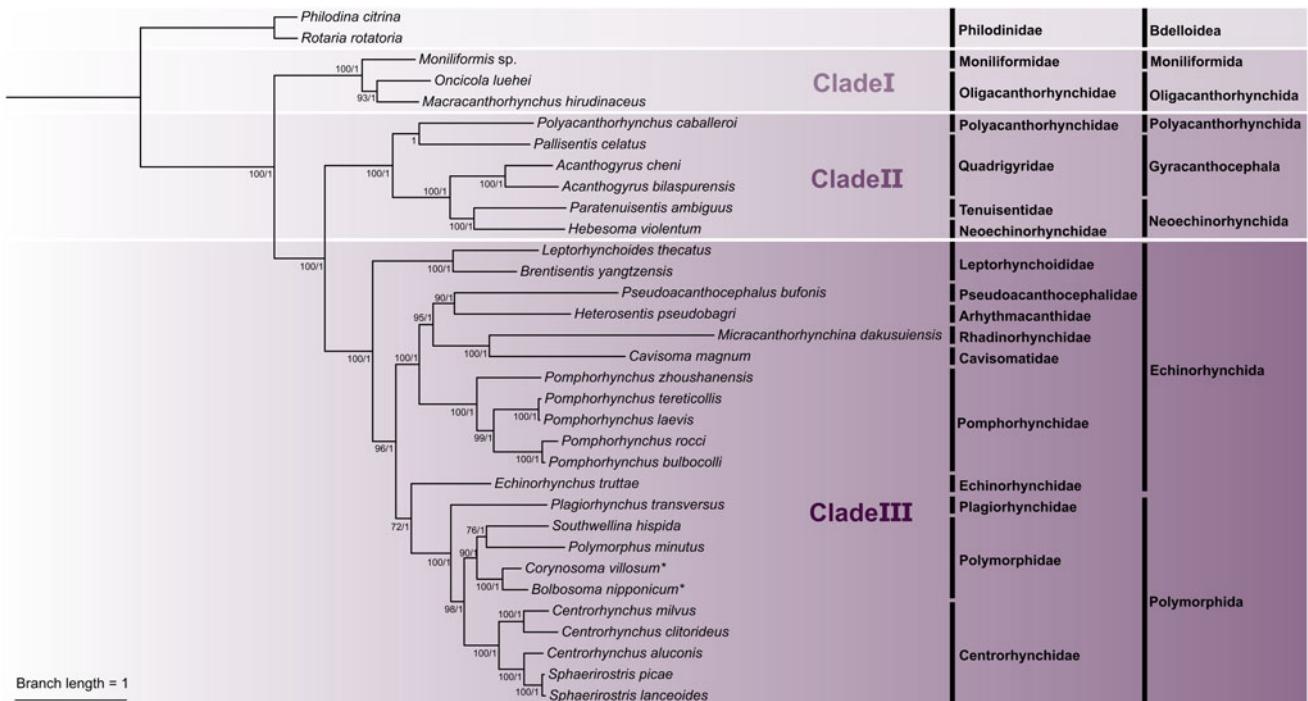

Figure 6. Phylogenetic analyses of Acanthocephala inferred from ML and BI methods based on concatenated amino acid sequences of 12 PCGs of mitochondrial genomes. *Rotaria rotatoria* and *Philodina citrina* were chosen as the out-group. Bootstrap values ≥ 70 and Bayesian posterior probabilities values ≥ 0.70 are shown in the phylogenetic trees. *Bolbosoma nipponicum* and *Corynosoma villosum* are indicated using asterisk (*).

Polymorphida), and also provided the resource of genetic data for diagnosing these 2 pathogenic parasites of human acanthocephaliasis.

Supplementary material. The supplementary material for this article can be found at <https://doi.org/10.1017/S0031182023001099>.

Data availability. The complete mitochondrial genomes of *B. nipponicum* and *C. villosum* obtained herein were deposited in the GenBank database (<http://www.ncbi.nlm.nih.gov>, under the accession numbers *Corynosoma villosum*: OR468095, *Bolbosoma nipponicum*: OR468096). Voucher specimens of *B. nipponicum* and *C. villosum* were deposited in the College of Life Sciences, Hebei Normal University, Hebei Province, China.

Acknowledgements. The authors are grateful to Professor Hideo Hasegawa (Faculty of Medicine, Oita University, Japan) for providing important literature. The authors wish to thank the people of the Aleut community and the National Marine Mammal Laboratory scientists for providing helps during collection of the parasites.

Author's contributions. D. X. L. and L. L. contributed to the study design and conducted the phylogenetic analyses. D. X. L., R. J. Y., H. X. C. and L. L. sequenced and analysed genetic data. H. X. C. and L. L. identified the acanthocephalan specimens. T. A. K. and T. R. S. provided acanthocephalan specimens. D. X. L. and L. L. wrote the manuscript. All authors read and approved the final manuscript.

Financial support. This study was supported by the National Natural Science Foundation of China (Grant No. 31872197) and the National Key R&D Program of China (Grant No. 2022YFC2601200).

Competing interest. None.

Ethical standards. This study was conducted under the protocol of Hebei Normal University. All applicable national and international guidelines for the protection and use of animals were followed.
