RANDOM EFFECT BIVARIATE SURVIVAL MODELS AND STOCHASTIC COMPARISONS

RAMESH C. GUPTA,* University of Maine
RAMESHWAR D. GUPTA,** University of New Brunswick

Abstract

In this paper we propose a general bivariate random effect model with special emphasis on frailty models and environmental effect models, and present some stochastic comparisons. The relationship between the conditional and the unconditional hazard gradients are derived and some examples are provided. We investigate how the well-known stochastic orderings between the distributions of two frailties translate into the orderings between the corresponding survival functions. These results are used to obtain the properties of the bivariate multiplicative model and the shared frailty model.

Keywords: Frailty model; environmental effect model; hazard gradient; bivariate multiplicative model; shared frailty model

2010 Mathematics Subject Classification: Primary 62N99; 62P99
Secondary 60E15

1. Introduction

Random effect models have been widely used in the context of linear models. In linear models, the random effect is introduced as the error variable and the distribution of this error variable is reflected in the parameter estimates and other inferential problems. Besides this, the random effect models have been used in survival analysis to model the heterogeneity unexplained by the covariates. In assessing the effect of environmental factors, these models have been used as random environmental models. The dependence structure created by the random effects in survival analysis is quite different than in the linear models. Recently, Rizopoulos et al. (2008), using the random effect model, investigated the association structure between a longitudinal response process and the time to an event of interest using the shared parameter framework.

As explained above, random effect models are used in different disciplines. We will present our results in the context of survival analysis or, more specifically, in the context of frailty models where the frailty is modeled as an unobservable random effect. Clayton (1978) and Clayton and Cuzick (1985) introduced the proportional hazard frailty model, where a group of observations is assigned a random effect that acts multiplicatively on the baseline hazard function. The proportional hazard frailty model implies conditional independence—conditional on the frailty terms, the event times are independent. However, unconditionally, they are dependent.
1.1. Frailty models

As is well known, a particularly useful tool in handling heterogeneity unexplained by the observed covariates is the ‘frailty model’, introduced in Vaupel et al. (1979). The classical frailty model is given by

\[ \lambda(t | v) = v \lambda_0(t), \quad t > 0, \]

where \( \lambda_0(t) \) is the baseline hazard independent of \( v \).

Model (1.1) states that the hazard rate of an individual is the product of the individual specific quantity \( v \) and the baseline hazard rate \( \lambda_0(t) \) describing the age effect. We consider \( v \lambda_0(t) \) to be the conditional failure rate of a random variable \( T \) given \( V = v \), where \( V \) is the frailty or mixing random variable. Frailty models have often been used when groups of subjects have responses that are likely to be dependent in some general way. For example, in an animal carcinogenicity study, the responses of members of the same litter are not likely to be independent. Liang et al. (1995) discussed the use of frailty models when multiple events have been observed on the same subject.

It is well known that the choice of frailty distribution strongly affects the estimate of the baseline hazard as well as the conditional probabilities; see Hougaard (1984), (1991), (1995), (2000, pp. 213–262), Heckman and Singer (1984), and Agresti et al. (2004). Since different distributions of frailty give rise to different population level distributions of analyzing survival data, it is appropriate to investigate how the comparative effect of two frailties translates into the comparative effect on the resulting distributions. In the shared frailty models, the assumptions about the frailty distributions play an important role in the model’s interpretation since the frailty distribution links the two processes of interest. For more discussion, see Rizopoulos et al. (2008) and Sargent (1998). In this connection, in the univariate case, Gupta and Kirmani (2006) investigated how well-known stochastic orderings between distributions of two frailties translate into orderings between the corresponding survival functions. More recently, in the univariate case, Gupta and Gupta (2009) studied a similar problem for a general frailty model which includes the classical frailty model (1.1) as well as the additive frailty model. It may be mentioned that, in the univariate setup, the above two papers reached results similar to the ones contained in the present paper.

For model (1.1), the population level hazard function is given by

\[ \lambda(t) = -\frac{d}{dt} \ln \bar{F}(t), \]

where

\[ \bar{F}(t) = P(T > t) = M_V(-\Lambda_0(t)), \]

\( M_V(\cdot) \) denotes the moment generating function of \( V \), and \( \Lambda_0(t) = \int_0^t \lambda_0(x) \, dx \).

The overall population hazard function \( \lambda(t) \) is related to the baseline hazard function \( \lambda_0(t) \) by the relation

\[ \lambda(t) = \lambda_0(t) \mathbb{E}(V | T > t). \]

Since

\[ \frac{d}{dt} \mathbb{E}(V | T > t) = -\lambda_0(t) \text{var}(V | T > t) \]

(see Gupta and Gupta (1996)), \( \lambda(t)/\lambda_0(t) \) is a decreasing function of \( t \). It can be seen that if \( \mathbb{E}(V) \leq 1 \) then \( \lambda(t) \leq \lambda_0(t), \quad t > 0 \), or, equivalently, \( \bar{G}(t)/\bar{F}(t) \) is decreasing on \([0, \infty)\), where \( \bar{G}(t) \) is the baseline survival function. In order to avoid identifiability problems, it is generally assumed that \( \mathbb{E}(V) = 1 \). In the case of gamma frailty, see Hougaard (2000, p. 233).
In this paper we study a general bivariate frailty model and present some stochastic comparisons using different distributions of the frailty. To this end, we define the bivariate hazard functions as follows.

Let \( T_1 \) and \( T_2 \) be two dependent random variables having absolutely continuous bivariate survival function \( \bar{F}(t_1, t_2) = P(T_1 > t_1, T_2 > t_2) \). Then the hazard (failure) rates, defined as

\[
\lambda^{(i)}(t_1, t_2) = -\frac{\partial}{\partial t_i} \ln \bar{F}(t_1, t_2), \quad i = 1, 2,
\]

are often used in demography, survival analysis, and biostatistics when analyzing bivariate survival data. Clearly, \( \lambda^{(1)}(t_1, t_2) \) is the hazard rate of \( T_1 \) given \( T_2 > t_2 \). Likewise, \( \lambda^{(2)}(t_1, t_2) \) is the hazard rate of \( T_2 \) given \( T_1 > t_1 \). The vector \( (\lambda^{(1)}(t_1, t_2), \lambda^{(2)}(t_1, t_2)) \) is called the hazard gradient. It is well known that the hazard gradient uniquely determines the survival function. Thus, we consider the general bivariate frailty model

\[
\lambda^{(i)}(t_1, t_2 | v) = \lambda^{(i)}(t_1, t_2, v), \quad i = 1, 2, \quad (1.2)
\]

where \( v \) is the frailty associated with an individual.

As mentioned earlier, our aim in this paper is to develop the properties of the general bivariate frailty model (1.2) and obtain some results for the stochastic comparisons using different frailty distributions. As a special case, we will obtain results for the classical bivariate frailty model and the shared frailty model. The organization of this paper is as follows. After giving the aims and objectives together with the necessary definitions and background, we describe the general bivariate frailty model along with some of the properties in Section 2. In Section 3, our main results lie in seeing how the well-known stochastic orderings between distributions of two frailties translate into the orderings between the corresponding survival functions. These results are used, in Section 4, to investigate the stochastic order properties of the multiplicative model and the shared frailty model. Finally, some conclusions and comments are given in Section 5.

Before proceeding further, we present some definitions and background for various stochastic comparisons.

**Definition.** Let \( X \) and \( Y \) be nonnegative absolutely continuous random variables with density functions \( f(x) \) and \( g(x) \), and survival functions \( \bar{F}(x) \) and \( \bar{G}(x) \), respectively. Then \( X \) and \( Y \) can be defined as follows.

(i) \( X \) is said to be smaller than \( Y \) in the likelihood ratio ordering, written as \( X \leq_{lr} Y \), if \( f(x)/g(x) \) is nonincreasing in \( x \).

(ii) \( X \) is said to be smaller than \( Y \) in the failure (hazard) rate ordering, written as \( X \leq_{fr} Y \), if \( r_F(x) \geq r_G(x) \) for all \( x \), where \( r_F(x) \) and \( r_G(x) \) are the hazard rates of \( X \) and \( Y \), respectively. This means that \( \bar{G}(x)/\bar{F}(x) \) increases in \( x \).

(iii) \( X \) is said to be smaller than \( Y \) in the stochastic ordering, written as \( X \leq_{st} Y \), if \( \bar{F}(x) \leq \bar{G}(x) \) for all \( x \).

(iv) \( X \) is said to be smaller than \( Y \) in the mean residual life ordering, written as \( X \leq_{mrl} Y \), if \( \mu_F(x) \leq \mu_G(x) \) for all \( x \). Deshpande et al. (1990) showed that \( X \leq_{mrl} Y \) if and only if \( \int_x^\infty \bar{F}(u) \, du / \int_x^\infty \bar{G}(u) \, du \) is decreasing in \( x \).

(v) Let \( X \) and \( Y \) be \( n \)-dimensional random vectors with hazard gradients

\[
(\lambda^{(1)}(x), \lambda^{(2)}(x), \ldots, \lambda^{(n)}(x)) \quad \text{and} \quad (\lambda^{(1)}(y), \lambda^{(2)}(y), \ldots, \lambda^{(n)}(y)),
\]

https://doi.org/10.1239/jap/1276784901 Published online by Cambridge University Press
respectively. Then $X \leq_{whr} Y$ (weak hazard rate order) if $\lambda_X^{(i)}(t) \geq \lambda_Y^{(i)}(t)$, $i = 1, 2, \ldots, n$ and $t \in \mathbb{R}^n$; see Shaked and Shanthikumar (2007, p. 271). Note that this condition is weaker than the hazard rate orderings of vectors.

The following relations are well known:

$$X \leq_{fr} Y \implies X \leq_{fr} Y \implies X \leq_{mt} Y \implies X \leq_{st} Y;$$

see Shaked and Shanthikumar (2007, p. 271).

2. General bivariate frailty model

Consider a general bivariate frailty model defined by the absolutely continuous joint survival function $F(t_1, t_2 | v)$, of a two-unit system, where $v$ is the frailty effect associated with the two variables. Define

$$\lambda^{(i)}(t_1, t_2 | v) = -\frac{\partial}{\partial t_i} \ln F(t_1, t_2 | v)$$

$$= -\frac{\partial}{\partial t_i} \ln \bar{F}(t_i | T_j > t_j, v)$$

$$= \frac{f(t_i | T_j > t_j, v)}{F(t_i | T_j > t_j, v)}, \quad i, j = 1, 2, \quad i \neq j.$$

That is, $\lambda^{(i)}(t_1, t_2 | v)$ is the failure rate function of the $i$th unit with the $j$th ($i \neq j$) unit surviving until time $t_j$, conditional on the frailty variable $V$.

If $h(v)$ denotes the probability density function (PDF) of the random environmental effect $V$, then the unconditional joint PDF and the survival function are

$$f(t_1, t_2) = \int_0^\infty f(t_1, t_2 | v)h(v) \, dv$$

and

$$\bar{F}(t_1, t_2) = \int_0^\infty \bar{F}(t_1, t_2 | v)h(v) \, dv,$$

respectively. These functions are known as the population level joint density and survival functions. The population level failure rate functions are defined as

$$\lambda^{(i)}(t_1, t_2) = -\frac{\partial}{\partial t_i} \ln \bar{F}(t_1, t_2)$$

$$= -\frac{\partial}{\partial t_i} \ln \bar{F}(t_i | T_j > t_j)$$

$$= \frac{f(t_i | T_j > t_j)}{\bar{F}(t_i | T_j > t_j)}, \quad i, j = 1, 2, \quad i \neq j.$$

In the following, we show that the population level hazard components are the averages of the conditional hazard components.
**Theorem 2.1.** The population level failure rate function of the $i$th unit in a two-unit system with the $j$th unit of fixed age $t_j$ is the expected value of $\lambda^{(i)}(t_1, t_2 \mid v)$ with respect to the conditional distribution of the frailty effect $V$ given $T_1 > t_1$ and $T_2 > t_2$. That is,

$$\lambda^{(i)}(t_1, t_2) = \mathbb{E}_{V \mid \{T_1 > t_1, T_2 > t_2\}}(\lambda^{(i)}(t_1, t_2 \mid v)), \quad i = 1, 2.$$  

It is assumed that the conditional distribution of $V$ given $T_1 > t_1$ and $T_2 > t_2$ is absolutely continuous, so that the conditional density exists.

**Proof.** We first show that

$$h(v \mid T_1 > t_1, T_2 > t_2) = \frac{\bar{F}(t_i \mid T_j > t_j, v) h(v)}{\bar{F}(t_i \mid T_j > t_j)}, \quad i = 1, 2, \quad i \neq j.$$  

Using (2.1). Thus, we have shown that

$$\lambda^{(i)}(t_1, t_2) = \mathbb{E}_{V \mid \{T_1 > t_1, T_2 > t_2\}}(\lambda^{(i)}(t_1, t_2 \mid v)), \quad i = 1, 2.$$  

Under a very mild condition, the following result addresses the monotonicity of the distribution (survival) function of the random effect as a function of the ages of the two units.
Theorem 2.2. If $\lambda^{(i)}(t_1, t_2 | v)$ is an increasing function of $v$, $i = 1, 2$, then $H(v | T_1 > t_1, T_2 > t_2)$ and $\bar{H}(v | T_1 > t_1, T_2 > t_2)$ are increasing and decreasing functions of $t_i$, respectively, where

$$H(v | T_1 > t_1, T_2 > t_2) = \int_0^v \frac{\bar{F}(t_i | T_j > t_j, u)h(u) \, du}{\bar{F}(t_i | T_j > t_j)}, \quad i, j = 1, 2, i \neq j,$$

is the conditional cumulative distribution function of the frailty variable among survivors and $\bar{H} = 1 - H$.

Proof. We have

$$\frac{\partial}{\partial t_i} H(v | T_1 > t_1, T_2 > t_2) = \frac{\int_0^v (\partial/\partial t_i) \bar{F}(t_i | T_j > t_j, u)h(u) \, du}{\bar{F}(t_i | T_j > t_j)} - \frac{\partial}{\partial t_i} \bar{F}(t_i, T_j > t_j)[\bar{F}(t_i, T_j > t_j)]^2 \int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du$$

$$= \frac{\int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du}{\bar{F}(t_i | T_j > t_j)} \left[ -A(v) + A(\infty) \right],$$

where

$$A(v) = \frac{\int_0^v \lambda^{(i)}(t_1, t_2 | u) \bar{F}(t_i | T_j > t_j, u)h(u) \, du}{\int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du}.$$

We now show that $A(v)$ is increasing in $v > 0$. We have

$$\frac{d}{dv} A(v) = \frac{1}{(\int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du)^2} \times \left( \left( \int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du \right) \lambda^{(i)}(t_1, t_2 | v) \bar{F}(t_i | T_j > t_j, v)h(v) \right.$$

$$- \bar{F}(t_i | T_j > t_j, v)h(v) \int_0^v \lambda^{(i)}(t_1, t_2 | u) \bar{F}(t_i | T_j > t_j, u)h(u) \, du \bigg)$$

$$= \frac{\bar{F}(t_i | T_j > t_j, v)h(v)}{(\int_0^v \bar{F}(t_i | T_j > t_j, u)h(u) \, du)^2} \times \left( \int_0^v [\lambda^{(i)}(t_1, t_2 | v) - \lambda^{(i)}(t_1, t_2 | u)] \bar{F}(t_i | T_j > t_j, u)h(u) \, du \right)$$

$$> 0,$$

since $\lambda^{(i)}(t_1, t_2 | v) > \lambda^{(i)}(t_1, t_2 | u)$ for all $u < v$.

Corollary 2.1. If $\lambda^{(i)}(t_1, t_2 | v)$ is an increasing function of $v$, $i = 1, 2$, then $E(V | T_1 > t_1, T_2 > t_2)$ is decreasing in $t_i$, $i = 1, 2$.

Proof. The hypothesis implies that $\bar{H}(v | T_1 > t_1, T_2 > t_2)$ is decreasing in $t_i > 0$. Thus,

$$E(V | T_1 > t_1, T_2 > t_2) = \int_0^\infty \bar{H}(v | T_1 > t_1, T_2 > t_2) \, dv$$

is decreasing in $t_i > 0$, $i = 1, 2$. 

https://doi.org/10.1234/jap/1276784901 Published online by Cambridge University Press
Remark 2.1. The statement of Corollary 2.1 is a precise statement of the heuristically obvious fact that the weaker units in the population fail earlier than the others, so the remaining units are more robust than the rest.

Remark 2.2. The condition \( \lambda(t_1, t_2 | v) \) is an increasing function of \( v \) will be satisfied by all the examples considered in the later sections.

The following results compare the frailty distribution of two groups, one with \( T_i > t_i \) and \( T_j > t_j \), and the other with \( T_i > t_i' \) and \( T_j > t_j' \), where \( t_{i1} < t_{i2}, i, j = 1, 2, i \neq j \).

Theorem 2.3. If \( \lambda(t_1, t_2 | v) \) is an increasing function of \( v \) then
\[
V \mid \{T_i > t_i, T_j > t_j\} \leq_{lr} V \mid \{T_i > t_i', T_j > t_j\}, \quad 0 < t_{i1} < t_{i2}, i = 1, 2.
\]

Proof. We have
\[
\frac{h(v \mid T_i > t_i, T_j > t_j)}{h(v \mid T_i > t_i', T_j > t_j)} = \frac{\bar{F}(t_{i2} \mid T_j > t_j, v)h(v)\bar{F}(t_{i1} \mid T_j > t_j)}{\bar{F}(t_{i1} \mid T_j > t_j, v)h(v)\bar{F}(t_{i2} \mid T_j > t_j)} = \exp \left\{ - \int_{t_{i1}}^{t_{i2}} \lambda(t_1, t_2 | u) \, du \right\} \frac{\bar{F}(t_{i1} \mid T_j > t_j)}{\bar{F}(t_{i2} \mid T_j > t_j)}.
\]
Since \( \lambda(t_1, t_2 | v) \) is an increasing function of \( v \), \( h(v \mid T_i > t_i, T_j > t_j)/h(v \mid T_i > t_i', T_j > t_j) \) is decreasing in \( v \). This means that the family of random variables \( V \mid \{T_i > t_i, T_j > t_j\} \) is decreasing in \( t_i > 0 \) in the sense of the likelihood ratio.

We now present a general result comparing a random variable with its weighted version.

Lemma 2.1. Let \( V_1 \) and \( V_2 \) be two random variables with density functions \( h_1(\cdot) \) and \( h_2(\cdot) \) such that
\[
h_2(v) = \int_0^\infty \frac{g(u)h_1(v)}{g(u)h_1(v) \, du}.
\]
where if \( g(v) \) is a decreasing function of \( v \) then \( V_1 \geq_{lr} V_2 \), and if \( g(v) \) is an increasing function of \( v \) then \( V_1 \leq_{lr} V_2 \).

Proof. Since \( h_2(v)/h_1(v) \) is nonincreasing in \( v \), the result follows by definition.

The following result shows how the ordering between two frailties is preserved for surviving individuals.

Theorem 2.4. Let \( V_1 \) and \( V_2 \) be two frailty random variables such that \( V_2 \leq_{lr} V_1 \). Then \( V_2 \mid \{T_1 > t_1, T_2 > t_2\} \leq_{lr} V_1 \mid \{T_1 > t_1, T_2 > t_2\} \).

Proof. We have
\[
H_2(v \mid T_1 > t_1, T_2 > t_2) = \int_0^v \bar{F}(t_1, t_2 \mid u)h_2(u) \, du
\]
\[
= \int_0^v \bar{F}(t_1, t_2 \mid u)g(u)h_1(u) \, du.
\]
This means that the distribution of \( V_2 \mid \{T_1 > t_1, T_2 > t_2\} \) is the weighted version of the distribution of \( V_1 \mid \{T_1 > t_1, T_2 > t_2\} \) by weight \( g(v) \), a decreasing function of \( v \). By applying Lemma 2.1 we obtain the result.
2.1. Examples

Suppose that

\[ \bar{F}(t_1, t_2 \mid v) = e^{-v \psi(t_1, t_2)}, \]

where \( \psi(t_1, t_2) \) is a differentiable function in both arguments such that \( \bar{F}(t_1, t_2 \mid v) \) is a conditional survival function.

Then

\[ \lambda^{(i)}(t_1, t_2 \mid v) = \frac{\partial}{\partial t_i} \psi(t_1, t_2), \quad i = 1, 2. \]

This gives (for \( i = 1, 2 \))

\[ \lambda^{(i)}(t_1, t_2) = E_{V \mid T_1 > t_1, T_2 > t_2}(\lambda^{(i)}(t_1, t_2 \mid v)) \]

\[ = \int_0^\infty v \frac{\partial}{\partial t_i} \psi(t_1, t_2) h(v \mid T_1 > t_1, T_2 > t_2) \, dv, \]

where \( h(v \mid T_1 > t_1, T_2 > t_2) \) is the PDF of \( V \) given \( T_1 > t_1 \) and \( T_2 > t_2 \). Thus,

\[ \lambda^{(i)}(t_1, t_2) = \frac{\partial}{\partial t_i} \psi(t_1, t_2) E(V \mid T_1 > t_1, T_2 > t_2) \]

\[ = \lambda_0^{(i)}(t_1, t_2) E(V \mid T_1 > t_1, T_2 > t_2), \]

where \( \lambda_0^{(i)}(t_1, t_2) (i = 1, 2) \) is the \( i \)th component of the hazard gradient without incorporating the frailty effect. Thus,

\[ \frac{\lambda^{(i)}(t_1, t_2)}{\lambda_0^{(i)}(t_1, t_2)} = E(V \mid T_1 > t_1, T_2 > t_2). \]

It can be verified that

\[ \frac{\partial}{\partial t_i} E(V \mid T_1 > t_1, T_2 > t_2) = -\lambda_0^{(i)}(t_1, t_2) \text{var}(V \mid T_1 > t_1, T_2 > t_2). \]

This means that \( \lambda^{(i)}(t_1, t_2) / \lambda_0^{(i)}(t_1, t_2) \) is a decreasing function of \( t_i, i = 1, 2 \).

2.1.1. Special case. If \( T_1 \) and \( T_2 \) are conditionally independent given the frailty, then \( \psi(t_1, t_2) = A_1(t_1) + A_2(t_2), \lambda_0^{(1)}(t_1, t_2) = A_1'(t_1), \) and \( \lambda_0^{(2)}(t_1, t_2) = A_2'(t_2), \) where the prime denotes the derivative.

The conditional survival function given \( V = v \) is

\[ \bar{F}(t_1, t_2 \mid v) = \exp[-v(A_1(t_1) + A_2(t_2))]. \]

The unconditional survival function is

\[ \bar{F}(t_1, t_2) = M_V[-(A_1(t_1) + A_2(t_2))], \]

where \( M_V(\cdot) \) is the moment generating function of \( V \).

In the following examples, we use this setup and assume that \( T_1 \) and \( T_2 \) are independent given the frailty variable.
2.1.2. Specific examples.

Example 2.1. Suppose that $V$ has a gamma distribution with PDF

$$h(v) = \frac{1}{\beta^\alpha \Gamma(\alpha)} v^{\alpha-1} e^{-v/\beta}, \quad v > 0, \; \alpha > 0, \; \beta > 0.$$  

So

$$\tilde{F}(t_1, t_2) = [1 + \beta A_1(t_1) + \beta A_2(t_2)]^{-\alpha}.$$  

The hazard components are given by

$$\lambda^{(i)}(t_1, t_2) = -\frac{\partial}{\partial t_i} \ln \tilde{F}(t_1, t_2) = \frac{\alpha \beta A'_i(t_i)}{1 + \beta A_1(t_1) + \beta A_2(t_2)}, \quad i = 1, 2.$$  

Furthermore,

$$E(V \mid T_1 > t_1, T_2 > t_2) = \frac{\alpha \beta}{1 + \beta A_1(t_1) + \beta A_2(t_2)}$$

and

$$\text{var}(V \mid T_1 > t_1, T_2 > t_2) = \frac{\alpha^2 \beta^2}{[1 + \beta A_1(t_1) + \beta A_2(t_2)]^2}.$$  

The above expressions yield the square of the coefficient of variation of $V$ given $T_1 > t_1$ and $T_2 > t_2$ as $\frac{1}{\alpha}$. It can be verified that a constant value of the coefficient of variation occurs only in the case of gamma frailty.

Example 2.2. Suppose that $V$ has an inverse Gaussian distribution with PDF

$$h(v) = \left(\frac{2}{\pi a v^3}\right)^{-1/2} \exp\left\{-\frac{(bv - 1)^2}{2av}\right\}, \quad v > 0, \; a > 0, \; b > 0.$$  

This gives

$$\tilde{F}(t_1, t_2) = \exp\left\{\frac{b}{a} \left(1 - \left(1 - \frac{2a}{b^2}(A_1(t_1) + A_2(t_2))\right)^{-1/2}\right)\right\}.$$  

The hazard components are given by

$$\lambda^{(i)}(t_1, t_2) = \frac{A_i(t_i)}{b^2 + 2a(A_1(t_1) + A_2(t_2))}^{1/2}, \quad i = 1, 2.$$  

Furthermore,

$$E(V \mid T_1 > t_1, T_2 > t_2) = \frac{1}{b^2 + 2a(A_1(t_1) + A_2(t_2))}^{1/2}$$

and

$$\text{var}(V \mid T_1 > t_1, T_2 > t_2) = \frac{a}{(b^2 + 2a(A_1(t_1) + A_2(t_2)))^{3/2}}.$$
3. Comparisons of frailty models

There is no firm basis for choosing the probability distribution of the frailty random variable \( V \). It is therefore important to see how the overall survival function of the \( i \)th unit, \( i = 1, 2 \), responds to the change in the probability distribution of \( V \). To be more precise, if the true model for the probability distribution of the frailty random variable is that of \( V_1 \) and the adopted model assumes the distribution of \( V_2 \), then we would like to know the relationship between the resulting random variables. Our main objective in this section is to see how some of the well-known stochastic orderings between \( V_1 \) and \( V_2 \) translate into the orderings between the component lifetimes.

**Theorem 3.1.** Let \( \lambda^{(i)}(t_1, t_2 | v) \) be an increasing function of \( v > 0 \), \( i = 1, 2 \). If \( V_2 \leq_{hr} V_1 \) then \((T_{11}, T_{21}) \leq_{whr} (T_{12}, T_{22}) \).

**Proof.** From (2.1) we have

\[
\lambda^{(i)}(t_1, t_2 | v) = \int_0^\infty \lambda^{(i)}(t_1, t_2 | u) h_1(u | T_1 > t_1, T_2 > t_2) \, du
- \int_0^\infty \lambda^{(i)}(t_1, t_2 | u) h_2(u | T_1 > t_1, T_2 > t_2) \, du
= \lambda^{(i)}(t_1, t_2 | u) [H_1(u | T_1 > t_1, T_2 > t_2) - H_2(u | T_1 > t_1, T_2 > t_2)]
- \int_0^\infty \frac{d}{du}\lambda^{(i)}(t_1, t_2 | u) [H_1(u | T_1 > t_1, T_2 > t_2) - H_2(u | T_1 > t_1, T_2 > t_2)] \, du
= \int_0^\infty \frac{d}{du}\lambda^{(i)}(t_1, t_2 | u) [H_2(u | T_1 > t_1, T_2 > t_2) - H_1(u | T_1 > t_1, T_2 > t_2)] \, du > 0.
\]

The rest of the proof follows by using the fact that \( \lambda^{(i)}(t_1, t_2 | v) \) is an increasing function of \( v \) and \( V_2 \leq_{hr} V_1 \).

Before presenting the next result, we give the following definition and the composition formula.

**Definition 3.1.** A real-valued function \( f(t, v) \) is said to be RR2 (reverse rule of order 2) or TP2 (total positive of order 2) on \([0, \infty) \times [0, \infty)\) if

\[
f(t_1, v_1) f(t_2, v_2) \leq f(t_1, v_2) f(t_2, v_1)
\]

or, respectively,

\[
f(t_1, v_1) f(t_2, v_2) \geq f(t_1, v_2) f(t_2, v_1)
\]

for all \( 0 < t_1 < t_2 \) and \( 0 < v_1 < v_2 \).

**Remark 3.1.** The concepts of RR2 and TP2 are used to study the dependence between two variables; see Karlin (1968, pp. 11–45).

The following statements are equivalent.

1. A real-valued function \( f(t, v) \) is RR2 on \([0, \infty) \times [0, \infty)\).
2. \( f(t, v_1)/f(t, v_2) \) is increasing in \( t > 0 \) and \( 0 < v_1 < v_2 \).
3. \( \partial^2 \ln f(t, v)/\partial t \partial v < 0 \).
4. \( f(t \mid v) \) or \( f(v \mid t) \) is RR2, where \( f(t \mid v) \) and \( f(v \mid t) \) are the conditional densities.

Similarly, the following statements are also equivalent.
1. A real-valued function \( f(t, v) \) is TP2 on \([0, \infty) \times [0, \infty)\).
2. \( f(t, v_1)/f(t, v_2) \) is decreasing in \( t > 0 \) and \( 0 < v_1 < v_2 \).
3. \( \partial^2 \ln f(t, v)/\partial t \partial v > 0 \).
4. \( f(t \mid v) \) or \( f(v \mid t) \) is TP2, where \( f(t \mid v) \) and \( f(v \mid t) \) are the conditional densities.

We now present the following result.

**Theorem 3.2.** Suppose that the conditional joint PDF of \( T_i \) and \( V \) given \( T_j > t_j, i, j = 1, 2, i \neq j \), is RR2. Then

(a) \( V \) is stochastically decreasing in the right tail with respect to \( T_i \), that is, \( \widetilde{H}(v \mid T_i > t_i, T_j > t_j, i \neq j) \) is a decreasing function of \( t_i, i = 1, 2 \);

(b) \( T_i \) is stochastically decreasing in the right tail with respect to \( V \), that is, \( \widetilde{F}(t_i \mid V > v, T_j > t_j, i \neq j) \) is a decreasing function of \( v \).

We now present the following well-known composition formula, which will be used in the sequel.

**Definition.** (Composition formula.) Let \( f(t, v) \) be an RR2 or TP2 function in \( t \in \mathbb{R} \) and \( v \in A \), and let \( h_i(v) \) be a TP2 function on \( \{1, 2\} \times A \), where \( h_i(v) \) is a probability density function in \( v \) for each \( i \). Then

\[
\Phi_i(t) = \int_A f(t, v) h_i(v) \, dv
\]

is RR2 or, respectively, TP2 on \( \{1, 2\} \times \mathbb{R} \). For a proof, see Karlin (1968).

The following result shows how the likelihood ratio ordering of \( V_1 \) and \( V_2 \) is inherited by \( T_1 \) and \( T_2 \).

**Theorem 3.3.** Suppose that \( V_1 \preceq_{LR} V_2 \). If \( f(t_i \mid v, T_j > t_j) \) is RR2 or TP2 on \([0, \infty) \times [0, \infty)\), then

\[
T_{i,v_1} \mid T_j > t_j \geq_{LR} T_{i,v_2} \mid T_j > t_j \quad \text{or, respectively,} \quad T_{i,v_1} \mid T_j > t_j \leq_{LR} T_{i,v_2} \mid T_j > t_j.
\]

**Proof.** The condition \( V_1 \preceq_{LR} V_2 \) implies that \( h_2(v)/h_1(v) \) is increasing in \( v > 0 \). That is, the map \((k, v) \mapsto h_k(v)\) is TP2 on \([1, 2] \times [0, \infty)\). If \( f(t_i \mid v, T_j > t_j) \) is RR2 or TP2 in \( t_i \) and \( v \) then, using the composition formula, the map \((k, t_i) \mapsto f_k(t_i \mid T_j > t_j)\) is RR2 or, respectively, TP2 on \([1, 2] \times [0, \infty)\), where \( f_k(t_i \mid T_j > t_j) \) is given by

\[
f_k(t_i \mid T_j > t_j) = \int_0^\infty f(t_i \mid u, T_j > t_j) h_k(u) \, du, \quad k = 1, 2.
\]

This implies that \( f_2(t_i \mid T_j > t_j)/f_1(t_i \mid T_j > t_j) \) is decreasing or, respectively, increasing.
in \( t_i > 0 \). Hence, \( T_{i,v_1} | T_j > t_j \geq_T T_{i,v_2} | T_j > t_j \) or, respectively, \( T_{i,v_1} | T_j > t_j \leq_T T_{i,v_2} | T_j > t_j \). This completes the proof.

The following result addresses the inheritance of failure rate orderings of \( V_1 \) and \( V_2 \) by \( T_1 \) and \( T_2 \).

**Theorem 3.4.** Suppose that

(a) \( V_1 \leq_T V_2 \); and

(b) \( \lambda^{(i)}(t_1, t_2 | v_1) \leq \lambda^{(i)}(t_1, t_2 | v_2) \) or \( \lambda^{(i)}(t_1, t_2 | v_1) \geq \lambda^{(i)}(t_1, t_2 | v_2) \), \( v_1 < v_2 \).

Then

\[
T_{i,v_1} | T_j > t_j \geq_T T_{i,v_2} | T_j > t_j, \quad i, j = 1, 2, i \neq j,
\]

or, respectively,

\[
T_{i,v_1} | T_j > t_j \leq_T T_{i,v_2} | T_j > t_j, \quad i, j = 1, 2, i \neq j.
\]

**Proof.** Since \( V_1 \leq_T V_2, \hat{H}_2(v)/\hat{H}_1(v) \) is increasing in \( v > 0 \), which is equivalent to the map \((k, v) \rightarrow \hat{H}_k(v) \) being TP2 on \([1, 2] \times [0, \infty)\). Condition (b) implies that \( \bar{F}(t_i | v, T_j > t_j) \) is RR2 or TP2 in \( t_i \) and \( v \) on \([0, \infty) \times [0, \infty)\). Also, (b) implies that

\[
\bar{F}(t_i | v_1, T_j > t_j) \geq \bar{F}(t_i | v_2, T_j > t_j)
\]

or, respectively,

\[
\bar{F}(t_i | v_1, T_j > t_j) \leq \bar{F}(t_i | v_2, T_j > t_j)
\]

for \( v_1 < v_2 \). This means that \( \bar{F}(t_i | v, T_j > t_j) \) is decreasing or, respectively, increasing in \( v \).

Define

\[
\bar{F}_k(t_i | T_j > t_j) = \int_0^\infty \bar{F}_k(t_i | u, T_j > t_j) h_k(u) \, du.
\]

Then the map \((k, t_i) \rightarrow \bar{F}_k(t_i | T_j > t_j)\) is RR2 or, respectively, TP2 on \([1, 2] \times [0, \infty)\). Therefore, \( \bar{F}_2(t_i | T_j > t_j)/\bar{F}_1(t_i | T_j > t_j) \) is a decreasing or, respectively, increasing function of \( t_i > 0 \). Hence, \( \lambda^{(i)}(t_1, t_2) \leq \lambda^{(i)}(t_1, t_2) \) or, respectively, \( \lambda^{(i)}(t_1, t_2) \geq \lambda^{(i)}(t_1, t_2) \) for all \( t_i > 0 \). That is

\[
T_{i,v_1} | T_j > t_j \geq_T T_{i,v_2} | T_j > t_j
\]

or, respectively,

\[
T_{i,v_1} | T_j > t_j \leq_T T_{i,v_2} | T_j > t_j.
\]

The following theorem shows the corresponding result for the stochastic orderings.

**Theorem 3.5.** If \( V_1 \leq_T V_2 \) and \( \bar{F}(t_i | v, T_j > t_j) \) is a decreasing function of \( v \), then \( T_{i,v_2} | T_j > t_j \leq_T T_{i,v_1} | T_j > t_j \), \( i, j = 1, 2, i \neq j \).

**Proof.** We have

\[
\begin{align*}
\bar{F}_2(t_i | T_j > t_j) &= \int_0^\infty \bar{F}(t_i | v, T_j > t_j) [\bar{H}_2(v) - \bar{H}_1(v)] \, dv \\
&= -\int_0^\infty \frac{d}{dv} \bar{F}(t_i | v, T_j > t_j) [\bar{H}_2(v) - \bar{H}_1(v)] \, dv \\
&\quad + \int_0^\infty \frac{d}{dv} \bar{F}(t_i | v, T_j > t_j) [\bar{H}_2(v) - \bar{H}_1(v)] \, dv \\
&= \int_0^\infty \frac{d}{dv} \bar{F}(t_i | v, T_j > t_j) [\bar{H}_2(v) - \bar{H}_1(v)] \, dv.
\end{align*}
\]
For model (4.1), the following statements hold.

**Theorem 4.1.** The random variable $\lambda^{(i)}(t_1, t_2 | v) = v\lambda_0^{(i)}(t_1, t_2)$, $t_1 > 0$, $t_2 > 0$, $v > 0,$ (4.1)

where $\lambda_0^{(i)}(t_1, t_2)$ is the baseline failure rate of the $i$th unit without taking into account the frailty effect and is independent of $v$. In this case

$$F(t_1, t_2 | v) = [\tilde{G}(t_1, t_2)]^v, \quad v > 0,$$

where $\tilde{G}(t_1, t_2)$ is the joint baseline survival function. This gives the unconditional survival function as

$$F(t_1, t_2) = \int_0^{\infty} [\tilde{G}(t_1, t_2)]^v h(v) \, dv, \quad v > 0,$$

where $h(v)$ is the PDF of the frailty effect $V$.

We now present the following result.

**Theorem 4.1.** For model (4.1), the following statements hold.

(a) The $i$th component of the population level failure rate is given by

$$\lambda^{(i)}(t_1, t_2) = \lambda_0(t_1, t_2) \, E_V(V | T_1 > t_1, T_2 > t_2).$$

(b) $H(v | T_1 > t_1, T_2 > t_2)$ is an increasing function of $t_1$, $i = 1, 2.$

(c) $E_V(V | T_1 > t_1, T_2 > t_2)$ is decreasing in $t_i > 0$, $i = 1, 2.$ Moreover, if $\lambda_0^{(i)}(t_1, t_2)$ is decreasing in $t_i > 0$ then $\lambda^{(i)}(t_1, t_2)$ is decreasing in $t_i > 0.$ That is, $T_i | T_j > t_j$, $i, j = 1, 2$, $i \neq j,$ is of decreasing failure rate.

(d) $V | \{T_i > t_2, T_j > t_j\} \leq \text{fr} V | \{T_i > t_1, T_j > t_j\}$ for all $t_1 < t_2, i, j = 1, 2, i \neq j.$

(e) If $V_2 \leq V_1$ then $V_2 \leq \text{fr} V_1.$

Proof. The proof of (a) follows from Theorem 2.1. For parts (b)–(e), since $\lambda^{(i)}(t_1, t_2 | v) = v\lambda_0^{(i)}(t_1, t_2)$ is an increasing function of $v,$ Theorems 2.2–2.3 and Corollary 2.1 apply.

We now present the following result, which addresses the monotonicity of the conditional survival function of the $i$th component given $V$ and the survival of the $j$th component.

**Theorem 4.2.** The random variable $T_i$ is stochastically decreasing in the right tail with respect to $V$ given $T_j > t_j$, $i = 1, 2.$ That is, $\tilde{F}(t_1 | v, T_j > t_j)$ is a decreasing function of $v > 0.$

Proof. We have

$$f(t_1 | v, T_j > t_j) = \lambda^{(i)}(t_1, t_2 | v) \tilde{F}(t_1 | v, T_j > t_j) = v\lambda_0^{(i)}(t_1, t_2) [\tilde{G}(t_1 | T_j > t_j)]^v.$$

If $0 < v_1 < v_2 < \infty$ then

$$\frac{f(t_1 | v_2, T_j > t_j)}{f(t_1 | v_1, T_j > t_j)} = \frac{v_2}{v_1} [\tilde{G}(t_1 | T_j > t_j)]^{v_2-v_1}$$
is a decreasing function of $t_i > 0$. Therefore, the conditional density of $T_i$ given $(v, T_j > t_j)$ is RR$_2$ in $t_i$ and $v$ on $[0, \infty) \times [0, \infty)$. Hence, the joint PDF of $T_j$ and $V$ given $T_j > t_j$ is RR$_2$. The result now follows from Theorem 3.2(b).

The following theorem shows how the stochastic comparisons between $V_1$ and $V_2$ translate into stochastic comparisons between $T_1$ and $T_2$.

**Theorem 4.3.** Let $A \in \{ \text{lr, fr, st} \}$. If $V_1 \leq_A V_2$ then

$$T_{i,v_1} | T_j > t_j \geq_A T_{i,v_2} | T_j > t_j, \quad i, j = 1, 2, i \neq j.$$

**Proof.** (a) Since $f(t_i | v, T_j, t_j)$ is RR$_2$ in $t_i$ and $v$, the result for lr follows from Theorem 3.4.

(b) Since $\lambda^{(i)}(t_1, t_2 | v) = v\lambda_0^{(i)}(t_1, t_2)$ is an increasing function of $v$, the result for fr follows from Theorem 3.4.

(c) Since $\bar{F}(t_i | v, T_j > t_j) = [\bar{G}(t_i | T_j > t_j)]^v$ is decreasing in $v > 0$, the result for st follows from Theorem 3.5.

4.1. Shared frailty model

We now consider the following model, known as the shared frailty model:

$$\lambda^{(i)}(t_1, t_2 | v) = v\lambda_0^{(i)}(t_i), \quad i = 1, 2,$$

where $\lambda_0^{(i)}(t_i)$ is the baseline failure rate of the $i$th unit, independent of the other unit and of $v$. In this case

$$\bar{F}(t_1, t_2 | v) = [\bar{G}^{(1)}(t_1)\bar{G}^{(2)}(t_2)]^v, \quad v > 0,$$

where $\bar{G}^{(i)}(t_i)$ is the baseline survival function of the $i$th unit. Thus,

$$\bar{F}(t_1, t_2) = \int_0^\infty [\bar{G}^{(1)}(t_1)\bar{G}^{(2)}(t_2)]^v h(v) \, dv,$$

where $h(v)$ is the PDF of $V$.

**Remark 4.1.** It is easily seen that the shared frailty model is a special case of the multiplicative model discussed above, and all the results of Theorems 4.1–4.3 apply.

**Remark 4.2.** A more general, shared random effect model has been studied in Rizopoulos et al. (2008), who investigated the association structure between a longitudinal response and survival processes.

5. Conclusion and comments

In this paper we presented a general bivariate random effect model. Random effect models are used in various disciplines. For example, in survival analysis they are used as frailty models and in problems related to the environment they are used as environmental effect models. We presented our results in the context of frailty models and studied their properties. We also investigated the effect on the survival by using two different frailty distributions. The corresponding results for the multiplicative and shared frailty models were also derived. The two examples presented illustrate the effect on the survival by incorporating the frailty effect. It is hoped that our results will be useful to researchers dealing with random effect models.
Acknowledgements
