# The Topological Interpretation of the Core Group of a Surface in $S^{4}$ 

Józef H. Przytycki and Witold Rosicki

#### Abstract

We give a topological interpretation of the core group invariant of a surface embedded in $S^{4}$ [F-R], [Ro]. We show that the group is isomorphic to the free product of the fundamental group of the double branch cover of $S^{4}$ with the surface as a branched set, and the infinite cyclic group. We present a generalization for unoriented surfaces, for other cyclic branched covers, and other codimension two embeddings of manifolds in spheres.

It is shown in [Ya-1] (compare [Ka-1], [C-S-2], [Ya-2]) that the fundamental group of the complement of an oriented surface, $M$, in $S^{4}$ allows a Wirtinger type presentation. In [Ro] the core group invariant of $M$ was introduced (following [F-R], [Joy]) and the topological interpretation of the group was promised. In the first section we give this interpretation following the result of Wada's [Wa] for classical knots and the proof of Wada result presented in [ Pr ]. In the second section we generalize our results to unoriented surfaces, and codimension two embeddings of closed $n$-manifolds in $S^{n+2}$.

## 1 Surfaces in $S^{4}$

Let $M$ be an oriented surface embedded in $S^{4}=R^{4} \cup\{\infty\}$. Let $p: R^{4} \rightarrow R^{3}$ be a projection such that the restriction to $M,\left.p\right|_{M}$ is a general position map. Define the lower decker set ("invisible" set) [C-S-1], [C-S-2] as $A=\{x \in M \mid \exists y \in M$, $p(x)=p(y)$ and $x$ is the lower point, that is x is further than y in the direction of the projection\}. The set $A$ separates $M$ into regions ("visibility" regions), that is arc connected components of $M-A$.

Theorem 1.1 ([Ya-1]) The fundamental group of $S^{4}-M\left(\Pi_{M}=\pi_{1}\left(S^{4}-M\right)\right)$ has the following Wirtinger type presentation. Generators of the group, $x_{1}, x_{2}, \ldots, x_{n}$, correspond to regions of $M$. Relations of the group correspond to double point arcs and are of the form $x_{i} x_{p} x_{i}^{-1} x_{q}^{-1}$ or $x_{i} x_{p}^{-1} x_{i}^{-1} x_{q}$, depending on the orientations of $p(M)$ at double point arcs. Here $x_{i}$ corresponds to the higher region of the projection and $x_{p}, x_{q}$ to lower regions.

Similarly to the group $\Pi_{M}$, we define the core group, $G_{M}$ of a surface $M$ in $S^{4}$.

[^0]Definition $1.2([\mathbf{R o}]) \quad$ The core group, $G_{M}$ of a surface $M$ in $S^{4}$, has the following, quandle type, presentation. Generators of the group, $y_{1}, y_{2}, \ldots, y_{n}$, correspond to regions of $M$. Relations of the group correspond to double point arcs and are of the form $y_{i} y_{p}^{-1} y_{i} y_{q}^{-1}$. Here $y_{i}$ corresponds to the higher region of the projection and $y_{p}, y_{q}$ to lower regions.

The operation $y_{p} * y_{i}=y_{i} y_{p}^{-1} y_{i}$ defines a quandle. We will interpret topologically the core group as follows. It is the analogue of the Wada result for classical links [Wa].

Theorem 1.3 The core group, $G_{M}$ of a surface $M$ in $S^{4}$, is isomorphic to the free product of the fundamental group of the branched double cover of $S^{4}$ with branching set $M$, and the infinite cyclic group. That is $G_{M}=\pi_{1}\left(M^{(2)}\right) * Z$ where $M^{(2)}$ is the considered double branched cover.

Below we will prove a generalization of the theorem for any cyclic branched cover, following the exposition of the classical case in [ Pr ].

Let $f: M^{(k)} \rightarrow S^{4}$ be a cyclic $k$-fold branched covering with a branch set $M$. More precisely $M^{(k)}$ is defined as follows: Let $V_{M}$ be a tubular neighborhood of $M$ in $S^{4}$. It has a structure of a 2 -disc bundle (over $M$ ). For a point $x \in M$ the boundary of the disk $D_{x}$ of the bundle is called a meridian of $M$ (at $\left.x\right)$, denoted by $\mu_{x}$. It has the natural orientation for oriented $M$. The first homology group of $S^{4}-M$ is freely generated by meridians of $M$ (one for each connected component of $M$ ). Thus, we have a $k$ fold cyclic covering of $S^{4}-M$ given by an epimorphism $H_{1}\left(S^{4}-M\right) \rightarrow Z_{k}$ which sends $\mu_{x}$ to 1 . This covering can be uniquely extended to the cyclic $k$-fold branched covering with a branch set $M$. Namely, we define the cover on each (meridian) disk $D_{x}$ as given by the function $p: D_{x}^{\prime} \rightarrow D_{x}, p(z)=z^{k}$ where $z$ is a complex coordinate of the disks.

Let $\Pi_{M}^{k}=\pi_{1}\left(M^{(k)}\right)$.

Proposition 1.4 Consider the epimorphism $\hat{g}_{k}: \pi_{1}\left(S^{4}-M\right) \rightarrow Z_{k}$ given by $\hat{g}_{k}\left(x_{i}\right)=1$ for any $i$. Then

$$
\Pi_{M}^{k}=\operatorname{ker}\left(\hat{g}_{k}\right) /\left(x_{i}\right)^{k} .
$$

Proof Consider a regular neighborhood of $M$ in $S^{4}$ and its normal disk bundle. Each disk in the bundle is covered by a disk (the center being a branch point). As noted before the covering can be described by the map $z \rightarrow z^{k}$ where $z$ is a complex coordinate of the disk. In the Wirtinger presentation of the fundamental group, generators correspond to some meridians (that is, boundaries of disks of the normal bundle).

Consider the unbranched $k$-covering of $S^{4}-M$ obtained by removing the branch set. The epimorphism $\hat{g}: \pi_{1}\left(S^{4}-M\right) \rightarrow Z_{k}$ corresponding to the covering sends each meridian to $1 \in Z_{k},\left(\hat{g}\left(\mu_{x}\right)=1\right)$. The fundamental group of the unbranched cover is equal to ker $\hat{g}$. To get a branched cover from the unbranched one we have to fill the cover of every meridian. On algebraic level we add relations $\mu_{x}^{k}=0$. Because every meridian is conjugated to a generator $x_{i}$, the proposition is proved.

Theorem 1.5 $\Pi_{M}^{(k)} * \underbrace{Z * \cdots * Z}_{k-1}=\Pi_{M \sqcup S^{2}}^{(k)}$ has the following quandle type description (in the disjoint sum $M \sqcup S^{2}, S^{2}$ is the unknotted component that can be separated by a 3-sphere from $M$ ).

To every (visible) region there correspond $k-1$ generators $\tau^{j}\left(y_{i}\right)(0 \leq j<k-1)$ and to each double point arc correspond $k-1$ relations $\tau^{j}\left(y_{p} \tau\left(y_{i}\right) \tau\left(y_{q}^{-1}\right) y_{i}^{-1}\right)$ or $\tau^{j}\left(y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1}\right)$ depending on a local orientation.

Lemma 1.6 Let $F_{n+1}=\left\{x_{1}, x_{2}, \ldots, x_{n+1} \mid\right\}$ be a free group of $n+1$ generators, $x_{1}, x_{2}, \ldots, x_{n+1}$. Consider the epimorphism $g_{k}: F_{n+1} \rightarrow Z_{k}$ such that $g_{k}\left(x_{i}\right)=1$ for any i. Let $F^{(k)}=\operatorname{ker}\left(g_{k}\right)$, and let $\bar{F}^{(k)}=F^{(k)} /\left(x_{i}^{k}\right)$. Let $\tau: F_{n+1} \rightarrow F_{n+1}$ be an automorphism, defined by $\tau\left(x_{i}\right)=x_{n+1} x_{i} x_{n+1}^{-1}$ and $y_{i}=x_{i} x_{n+1}^{-1}$. Then
(i) $F^{(k)}$ is a free group of $n k+1$ generators: $x_{n+1}^{k}$ and $\tau^{j}\left(y_{i}\right)$ for $0 \leq j \leq k-1$, $1 \leq i \leq n$.
(ii) $\bar{F}^{(k)}$ is a free group on $n(k-1)$ generators $\tau^{j}\left(y_{i}\right)$ for $0 \leq j<k-1,1 \leq i \leq n$. Furthermore $y_{i} \tau\left(y_{i}\right) \cdots \tau^{k-1}\left(y_{i}\right)=1$ for any $i$.

Figure 1: The covering $\tilde{T}_{4}^{(8)} \rightarrow T_{4}$

Proof (i) $F_{n+1}=\pi_{1}\left(T_{n+1}\right)$ where $T_{n+1}$ is a graph of one vertex and $n+1$ loops (Fig. 1(a)). $g_{k}: F_{n+1} \rightarrow Z_{k}$ determines a $k$-fold covering space $\tilde{T}_{n+1}^{(k)}$ of the graph $T_{n+1}$ as shown in Fig. 1(b). Of course, the Euler characteristic $\chi\left(T_{n+1}\right)=-n$ and $\chi\left(\tilde{T}_{n+1}^{(k)}\right)=-k n$. Thus, $\pi_{1}\left(\tilde{T}_{n+1}^{(k)}\right)$ is freely generated by $n k+1$ generators. We can easily
identify free generators of $\pi_{1}\left(\tilde{T}_{n+1}^{(k)}\right)=\operatorname{ker} g_{k}$; in particular, $g_{k}\left(x_{n+1}^{k}\right)=g_{k}\left(\tau^{j}\left(y_{i}\right)\right)=$ 0 for $1 \leq i \leq n$ and $0 \leq j \leq k-1$.
(ii) $y_{i} \tau\left(y_{i}\right) \tau^{2}\left(y_{i}\right) \cdots \tau^{k-1}\left(y_{i}\right)=\left(x_{i} x_{n+1}^{-1}\right)\left(x_{n+1} x_{i} x_{n+1}^{-2}\right) \cdots\left(x_{n+1}^{k-1} x_{i} x_{n+1}^{-k}\right)=x_{i}^{k} x_{n+1}^{-k}$. Thus, in $F_{n+1}^{(k)} /\left(x_{n+1}^{k}\right)$ we have $y_{1} \cdots \tau^{k-1}\left(y_{i}\right)=x_{i}^{k}$ and furthermore

$$
\begin{aligned}
\bar{F}_{n+1}^{(k)} & =\left\{F_{n+1}^{(k)} \mid x_{n+1}^{k}, x_{i}^{k} ; 1 \leq i \leq n\right\} \\
& =\left\{x_{n+1}^{k}, \tau^{j}\left(y_{i}\right) \mid x_{n+1}^{k}, y_{i} \tau\left(y_{i}\right) \cdots \tau^{k-1}\left(y_{i}\right), 1 \leq i \leq n, 0 \leq j \leq k-1\right\} \\
& =\left\{\tau^{j}\left(y_{i}\right) \mid y_{i} \tau\left(y_{i}\right) \cdots \tau^{k-1}\left(y_{i}\right), 1 \leq i \leq n, 0 \leq j \leq k-1\right\} \\
& =\left\{\tau^{j}\left(y_{i}\right) \mid 1 \leq i \leq n, 0 \leq j<k-1\right\}
\end{aligned}
$$

as required.
We will use an extension of Lemma 1.6 for a group with Wirtinger type relations.
Let $G=\left\{F_{n} \mid r_{1}, \ldots, r_{m}\right\}=\left\{x_{1}, \ldots, x_{n} \mid r_{1}, \ldots, r_{m}\right\}$ where any relation is of the form $r=x_{i} x_{p}^{\epsilon} x_{i}^{-1} x_{q}^{-\epsilon}$ for $\epsilon= \pm 1$, and $1 \leq i, p, q \leq n$.

We have $G * Z=\left\{x_{1}, \ldots, x_{n+1} \mid r_{1}, \ldots, r_{m}\right\}$. The epimorphism $g_{k}: F_{n+1} \rightarrow Z_{k}$ yields the epimorphism $\hat{g}_{k}: G * Z \rightarrow Z_{k}$. The epimorphism $\hat{g}_{k}$ is well defined because $g_{k}\left(r_{i}\right)=0$. We use Lemma 1.6 to find a presentation of $G^{(k)}=\operatorname{ker} \hat{g}_{k}$ and $\bar{G}^{(k)}=$ $G^{(k)} /\left(x_{i}^{k}\right)$.

## Lemma 1.7

(i) $\quad G^{(k)}=\left\{F^{(k)} \mid \tau^{j}\left(r_{s}\right), 1 \leq s \leq m, 0 \leq j \leq k-1\right\}$.
(ii) $\bar{G}^{(k)}=\left\{\bar{F}^{(k)} \mid \tau^{j}\left(r_{s}\right), 1 \leq s \leq m, 0 \leq j<k-1\right\}=\left\{\tau^{j}\left(y_{i}\right) \mid \tau^{j}\left(r_{s}\right), 1 \leq s \leq\right.$ $m, 0 \leq j<k-1,1 \leq i \leq n\}$ where $\tau^{j}\left(x_{i} x_{p} x_{i}^{-1} x_{q}^{-1}\right)=\tau^{j}\left(y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1}\right)$ and $\tau^{j}\left(x_{i} x_{p}^{-1} x_{i}^{-1} x_{q}\right)=\tau^{j}\left(y_{i} y_{p}^{-1} \tau^{-1}\left(y_{i}^{-1}\right) \tau^{-1}\left(y_{q}\right)\right)$.

Proof (i) Because $r_{s} \in \operatorname{ker} g_{k}$ then the relations of ker $\hat{g}_{k}$ are of the form $w r_{i} w^{-1}$ for $w \in F_{n+1}$. We observe that if $g_{k}(w)=u(0 \leq u \leq k-1)$ then $w=x_{n+1}^{u} w^{\prime}$ where $w^{\prime} \in \operatorname{ker} g_{k}$. Therefore relations of $G^{(k)}=\operatorname{ker} \hat{\hat{g}_{k}}$ are of the form $\tau^{u}\left(r_{s}\right)$ for $0 \leq u \leq k-1,1 \leq s \leq m$. These yield the presentation of $G^{(k)}$. We have:

$$
\begin{aligned}
x_{i} x_{p} x_{i}^{-1} x_{q}^{-1} & =\left(x_{i} x_{n+1}^{-1}\right)\left(x_{n+1}\left(x_{p} x_{n+1}^{-1}\right) x_{n+1}^{-1}\right)\left(x_{n+1}\left(x_{n+1} x_{i}^{-1}\right) x_{n+1}^{-1}\right)\left(x_{n+1} x_{q}^{-1}\right) \\
& =y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1} \\
x_{i} x_{p}^{-1} x_{i}^{-1} x_{q} & =\left(x_{i} x_{n+1}^{-1}\right)\left(x_{n+1} x_{p}^{-1}\right)\left(x_{i}^{-1} x_{n+1}\right)\left(x_{n+1}^{-1} x_{q}\right) \\
& =y_{i} y_{p}^{-1}\left(\tau^{-1}\left(y_{i}\right)\right)^{-1} \tau^{-1}\left(y_{q}\right)
\end{aligned}
$$

(ii) Adding relations $\left(x_{i}\right)^{k}$ reduces $F^{(k)}$ to $\bar{F}^{(k)}$ and $G^{(k)}$ to $\bar{G}^{(k)}$ so $\bar{G}^{(k)}=\left\{\bar{F}^{(k)} \mid\right.$ $\left.\tau^{j}\left(r_{s}\right), 1 \leq s \leq m, 0 \leq j \leq k-1\right\}$. We can eliminate the relation $\tau^{k-1}\left(r_{s}\right)$ (expressing it using other relations). We use the identity $y_{i} \tau\left(y_{i}\right) \cdots \tau^{k-1}\left(y_{i}\right)=1$ in $\bar{G}^{(k)}$ (in particular $\left.\tau^{k}\left(y_{i}\right)=y_{i}\right)$. We can write our relations $\tau^{u}\left(y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1}\right)$ as
$\tau^{u+1}\left(y_{p} y_{i}^{-1}\right)=\tau^{u}\left(y_{i}^{-1} y_{q}\right)$. We assume it holds for $0 \leq u<k-1$ and we will see that $\tau^{k-1}\left(r_{s}\right)=1$ as well:

$$
\begin{aligned}
\tau^{k-1} & \left(y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1}\right) \\
& =\tau^{k-1}\left(y_{i}\right) \tau^{k}\left(y_{p}\right) \tau^{k}\left(y_{i}^{-1}\right) \tau^{k-1}\left(y_{q}^{-1}\right) \\
& =\tau^{k-1}\left(y_{i}\right) y_{p} y_{i}^{-1} \tau^{k-1}\left(y_{q}^{-1}\right) \\
& =\tau^{k-1}\left(y_{i}\right) y_{p}\left(y_{i}^{-1} y_{q}\right) \tau\left(y_{q}\right) \cdots \tau^{k-2}\left(y_{q}\right) \\
& =\tau^{k-1}\left(y_{i}\right) y_{p} \tau\left(y_{p}\right)\left(\tau\left(y_{i}^{-1}\right) \tau\left(y_{q}\right)\right) \tau^{2}\left(y_{q}\right) \cdots \tau^{k-2}\left(y_{q}\right) \\
& =\tau^{k-1}\left(y_{i}\right) y_{p} \tau\left(y_{p}\right) \tau^{2}\left(y_{p}\right)\left(\tau^{2}\left(y_{i}^{-1}\right) \tau^{2}\left(y_{q}\right)\right) \tau^{3}\left(y_{q}\right) \cdots \tau^{k-2}\left(y_{q}\right) \\
& =\tau^{k-1}\left(y_{i}\right) y_{p} \tau\left(y_{p}\right) \tau^{2}\left(y_{p}\right) \tau^{3}\left(y_{p}\right) \cdots \tau^{k-1}\left(y_{p}\right) \tau^{k-1}\left(y_{i}^{-1}\right) \\
& =1
\end{aligned}
$$

as required.
Theorem 1.5 follows from Proposition 1.4 and Lemma 1.7. In particular, Theorem 1.3 follows because for $k=2$ we have $y_{i} \tau\left(y_{i}\right)=1$ so $\tau\left(y_{i}\right)=y_{i}^{-1}$. In the next section, we show that the recent result of Kamada [Ka-2] allows us to extend Theorem 1.5 to any closed oriented $n$-manifold in $S^{n+2}$. Similarly Theorem 1.3 can be generalized to any closed unoriented $n$-manifold in $S^{n+2}$.

## 2 Higher Dimensional Case: $M^{n} \subset S^{n+2}$

We can extend our results to the case of a closed $n$-manifold $M$ in $S^{n+2}$ (not necessary oriented or connected). First we need an existence of the Wirtinger type presentation of the fundamental group of $S^{n+2}-M$ for oriented $M$, described in [Ka-2] and its variant for unoriented $M$.

Theorem 2.1 ([Kamada]) Let $p: R^{n+2} \rightarrow R^{n+1}$ be a projection and $M$ be in general position with respect to the projection. We can think that the base point is very high above $R^{n+1}$ (say at $\infty \in S^{n+2}$ ). We have $n-1$ dimensional strata being the closure of the (invisible) set $\{x \in M \mid \exists y \in M, p(x)=p(y)$ and $x$ is the lower point $\}$. These strata cut $M$ into $n$-dimensional regions ("visibility regions"). Let $\Pi_{M}$ denote the fundamental group of $S^{n+2}-M\left(\Pi_{M}=\pi_{1}\left(S^{n+2}-M\right)\right)$.
(1) Assume that $M$ is oriented.

Then $\Pi_{M}$ has the following Wirtinger type presentation. Generators of the group, $x_{1}, x_{2}, \ldots, x_{n}$, correspond to regions of $M$ (and can be visualize by joining the base point $b$ to any meridian of the region; meridians are oriented so elements of $\Pi_{M}$ are well defined). Relations of the group correspond to double point strata and are of the form $x_{i} x_{p} x_{i}^{-1} x_{q}^{-1}$ or $x_{i} x_{p}^{-1} x_{i}^{-1} x_{q}$, depending on orientations of $p(M)$ at double point strata. Here $x_{i}$ corresponds to the higher region of the projection and $x_{p}, x_{q}$ to lower regions.
(2) Consider now $M$ not necessary oriented. Let generators, $x_{1}, x_{2}, \ldots, x_{n}$ be chosen as before (one for each region). Because a region may be unorientable we have to make choices here. However, modulo relations $x_{i}^{2}=1$ (for $1 \leq i \leq n$ ), the group has Wirtinger type presentation. That is: $\Pi_{M} /\left(x_{i}^{2}\right)$ has a presentation as in (1) with additional relations $x_{i}^{2}=1$.

In the unoriented case meridians have no preferred orientation so only the branched double cover is uniquely defined, so we can interpret the core group of the embedded unoriented codimension two submanifold of $S^{n+2}$.

Kamada's theorem allows us to generalize Theorems 1.3 and 1.5. The proof, as before, bases on Lemma 1.7 ( $k=2$ yields an unoriented case), so we omit it.

Let $p: R^{n+2} \rightarrow R^{n+1}$ be a projection and $M$ be an $n$-dimensional closed submanifold of $R^{n+2}$ (and $S^{n+2}=R^{n+2} \cup \infty$ ) being in general position with respect to the projection. Using notation of Theorem 2.1 we have:

Theorem 2.2 Let $M^{(k)}$ denote the cyclic branched regular $k$-covering of $S^{n+2}$ with an oriented manifold $M$ as a branched set, and $\Pi_{M}^{(k)}$ its fundamental group. Then $\Pi_{M}^{(k)} *$ $\underbrace{Z * \cdots * Z}_{k-1}=\Pi_{M \sqcup S^{n}}^{(k)}$ has the following quandle type description.

To every region corresponds $k-1$ generators $\tau^{j}\left(y_{i}\right)(0 \leq j<k-1)$ and to each double point strata correspond $k-1$ relations $\tau^{j}\left(y_{p} \tau\left(y_{i}\right) \tau\left(y_{q}^{-1}\right) y_{i}^{-1}\right)$ or $\tau^{j}\left(y_{i} \tau\left(y_{p}\right) \tau\left(y_{i}^{-1}\right) y_{q}^{-1}\right)$ depending on a local orientation.

Theorem 2.3 Let $M^{(2)}$ denote the double branched regular 2-covering of $S^{n+2}$ with an unoriented (possibly not orientable) manifold $M$ as a branched set. Then $\pi_{1}\left(M^{(2)}\right) * Z=$ $\Pi_{M \cup S^{n}}^{(2)}$ has the following core (quandle type) description.

Generators of the group, $y_{1}, y_{2}, \ldots, y_{n}$, correspond to regions of M. Relations of the group correspond to double point strata and are of the form $y_{i} y_{p}^{-1} y_{i} y_{q}^{-1}$.

In the case of a 3-manifold in $S^{5}$, one can check invariantness of our groups, defined combinatorically, using the Roseman moves [Ros-1].

Acknowledgment We would like to thank Prof. L. Kauffman for his encouragement to work on the above problems after the talk of the second author at the Knots in Hellas 98 conference.
