Ireland represents a positive paradigm shift in training toward a return to the psychotherapeutic, rather than solely prescribing, role of the psychiatrist.

Melissa Gill is senior registrar in general adult psychiatry at Cavan Mental Health Service, Cavan, Ireland, email: melissa.gill@hse.ie, and MacDara McCauley is consultant general adult psychiatrist at St Brigid’s Hospital, Ardee, Co Louth, Ireland.

The capacity to attain subjectivity and emotion: the value of continuity of care

In a refreshing and thought-provoking editorial, Yakeley et al remind us about the concept of subjectivity. ‘Affective subjectivity’ is defined as ‘the awareness of and reflection on our emotional responses and their influence on our work, and the development of a capacity for self-reflection and emotional attunement with our patients’. The authors list a number of factors that have led to a reduction in the capacity of psychiatrists to develop and use affective subjectivity. One of these is the loss of continuity of care.

Over the past 10 years we have seen a gradual erosion of the capacity to offer continuity of care to our patients. Psychiatric teams are now fragmented, specialist and largely separate. This enhances splitting within and between teams and makes it difficult for patients to be held in mind for very long.

When I trained as a house officer and junior psychiatrist in the early 1990s, continuity of care was awarded so much importance across the medical specialties that we worked extremely long hours to offer this. An in-depth knowledge of your patient was expected and great emphasis was placed on personally following up their progress and seeing it through. While the long hours were far from ideal, the pendulum has swung so far back that continuity of care is now largely gone. All too often the concept of holistic care is being replaced by separate. This enhances splitting within and between teams and makes it difficult for patients to be held in mind for very long.

The formation of delusions is associated with a ‘jumping to conclusions’ cognitive bias. This can result in an intolerance of uncertainty and anomalous interpretations of internal or external stimuli. There is renewed focus on the ways in which affective processes can contribute to the formation of delusions and how these mechanisms can be modified using cognitive–behavioural techniques. These insights from cognitive neuropsychology are substantiated by neuroimaging studies. The salience network, an intrinsic large-scale cerebral network, shows strong connectivity between the anterior cingulate gyrus and insular cortex. This network enables switching between different dynamic brain states. Dysfunction in this network has been implicated in the formation of the key symptoms of psychosis: inappropriate salience attached to ambiguous stimuli can predispose to and perpetuate unusual

Challenges and opportunities in (neuro)psychiatry

It would appear that British psychiatry is retreating to a neurophobic position. The disconnect between psychiatry and its medical foundations is further exacerbated by the lack of medical experience in specialties relevant to psychiatry such as neurology, endocrinology and geriatric medicine. This is related to the constraints placed on training by service provision and the separation of psychiatric and medical services. The Future of Mental Health Services Report, headed by Prof. Dinesh Bhugra in collaboration with the Mental Health Foundation, called for greater collaboration between psychiatric and general medical services.

Elucidating the nature of mental illness and developing effective treatments requires enthusiastic and talented academics and clinicians. Instead of ideological turf wars, collaboration between disciplines is required to appreciate the nuanced interactions between genetics, biochemistry and the environment.

For example, the classical distinction between affective and psychotic experiences is becoming increasingly blurred. The formation of delusions is associated with a ‘jumping to conclusions’ cognitive bias. This can result in an intolerance of uncertainty and anomalous interpretations of internal or external stimuli. There is renewed focus on the ways in which affective processes can contribute to the formation of delusions and how these mechanisms can be modified using cognitive–behavioural techniques. These insights from cognitive neuropsychology are substantiated by neuroimaging studies. The salience network, an intrinsic large-scale cerebral network, shows strong connectivity between the anterior cingulate gyrus and insular cortex.
