Abstract. We show that the detection of double-barred (S2B) galaxies beyond the nearby universe is possible out to redshifts $0.1 \lesssim z \lesssim 0.5$ with the resolution of the \textit{HST} Advanced Camera for Surveys. We present the most distant S2B currently known, at $z = 0.148$.

Keywords. Galaxies: structure, galaxies: distances and redshifts, galaxies: evolution

Double-barred (S2B) galaxies could be a mechanism for feeding supermassive black holes by funneling gas to the center (Shlosman \textit{et al.} 1990). Until recently, S2Bs had only been identified in the nearby ($z \leq 0.04$) universe, which led us to perform a feasibility study for detecting and analysing them at intermediate redshifts (Lisker \textit{et al.} 2006) with the \textit{HST} Advanced Camera for Surveys (ACS) data of the Great Observatories Origins Deep Survey (Giavalisco \textit{et al.} 2004). We identified the two most distant S2Bs known so far, at redshifts $z = 0.103$ and $z = 0.148$ (Figs. 1 & 2), corresponding to a look-back time of 1.3 and 1.9 Gyr, respectively. Based on local S2B sizes, deep \textit{HST}/ACS and similar surveys have the potential to push the limit for S2B detection out to a look-back time of 5 Gyr. An S2B sample distributed over a large redshift range therefore seems possible in the near future, which would serve as important constraint on S2B formation models.
