ABSTRACT

In this paper, field effect transistors (FET) based on different kinds of non-graphene materials are introduced, which are MoS2, WSe2 and black phosphorus (BP). Those devices have their unique features in fabrication process compared with conventional FETs. Among them, MoS2 FET shows better electrical characteristics by applying a SiO2 protective layer; WSe2 FET is fabricated based on a new low pressure chemical vapor deposition (LPCVD) method; BP FET acquires high on/off ratio and high hole mobility by using a simple dry transfer method. Those novel non-graphene materials inspire new design and fabrication process of basic logic device.

INTRODUCTION

Field effect transistor (FET) as the basic logic device plays an important role in information age. Novel two-dimensional (2D) materials show great promise for the next generation low-dimensional FET. However, the FET based on a well-known 2D material, graphene, shows bad on-off radio due to its zero bandgap property. Therefore, beyond graphene, new kinds of non-graphene materials with reasonable bandgap, such as MoS2, WSe2 and black phosphorus (BP), have attracted wide research attention. Unique FET fabrication process was designed for these non-graphene 2D materials to obtain FET with higher mobility and on-off ratio. Here, three works about novel field effect transistor fabrication based on non-graphene 2D materials are presented and discussed.

MoS2 FETs with a SiO2 protective layer

A. Introduction

Top-gate MoS2 FETs with SiO2 protective layer were fabricated to avoid the monolayer MoS2 from the influence of charged impurities and interface states by designing unique optical lithography process. As a result, the contact property between the MoS2 and the electrodes were improved and both the carrier mobility and the source-drain current were enhanced. Comparing with MoS2 FETs without a SiO2 protective layer, the SiO2 protective layer was found to enhance the transfer and output characteristics of MoS2 FETs. This work applies a practical method to enhance the MoS2 FETs performance in the low-dimensional FET fabrication process.

B. Monolayer MoS2 characterization and device fabrication
The details of monolayer MoS\(_2\) growth on SiO\(_2\)/Si substrate by CVD method were referred in Ref.1.\(^{[1]}\) The AFM image in Figure 1 (a) shows the uniformity of the MoS\(_2\) material with a thickness of \(\sim 0.71\) nm, which accords with the thickness of monolayer MoS\(_2\) well. The red and blue lines in the Figure 1 (b) present the Raman spectrum of MoS\(_2\) material before and after 10 s buffer oxide etching (BOE) process, which are nearly overlapped and indicate that the BOE liquid did not etch the MoS\(_2\) layer. The difference of the two peak in the Ramon spectrum is 19.5 cm\(^{-1}\), which demonstrates the MoS\(_2\) layer is a monolayer.

Two different MoS\(_2\) FETs structures with and without 10 nm SiO\(_2\) protective layer were shown in Figure 1 (c) and (d), respectively. Figure 2 shows the fabrication process of the MoS\(_2\) FETs structure with a SiO\(_2\) protective layer. 10 nm SiO\(_2\) layer was deposited on the MoS\(_2\) surface by ALD to protect the MoS\(_2\) layer from being exposed to the photoresist and other object. By the first lithography step, extra SiO\(_2\) protective layer was etched using 10s BOE process and 25 nm Ti electrodes were deposited on the MoS\(_2\) layer. After the second lithography, the extra SiO\(_2\) and MoS\(_2\) layer were etched by the second BOE process and O\(_2\) plasma, respectively. Finally, the high-k HfO\(_2\) dielectric and Al top gate electrodes were made by conventional fabrication process and MoS\(_2\) FETs structures with SiO\(_2\) protective layer were achieved.

(b) Patterning the metal electrodes and etched SiO$_2$ by BOE liquid. (c) The SiO$_2$ layer was etched. (d) Depositing 25nm Ti metal by lift-off. (e) Etching SiO$_2$ by BOE liquid and etching MoS$_2$ material by O$_2$ plasma. (f) The MoS$_2$ was etched. (g) Depositing top-gate dielectric 30nm HfO$_2$ by ALD. (h) Etching the HfO$_2$ to expose the source/drain electrodes and depositing top-gate electrode Al.

C. Electrical characterization of MoS$_2$ FETs with a SiO$_2$ protective layer

Figure 3 shows the measured electronic characteristics of a top-gate monolayer MoS$_2$ FET with a SiO$_2$ protective layer, whose channel length and width are both 4 μm. Figure 3 (a) shows the transfer characteristics (red line) of the FET at $V_{ds} = 1$ V in which the drain-source current ($I_{ds}$) varies as a function of top-gate voltage ($V_{gs}$). At $V_{ds} = 1$ V, the current on/off radio is $\sim 5 \times 10^6$ and the FET mobility ($\mu$) calculated by the equation:

$$\mu = \frac{dI_{ds}}{dV_{gs}} \cdot \frac{L}{W} \cdot \frac{1}{C_{ox} \cdot V_{ds}}$$

The FET mobility is $\sim 42.3$ cm$^2$/V·S, which has increased $\sim 20$ times compared to the previous MoS$_2$ FET fabricated without the SiO$_2$ protective layer. Figure 4 (b) shows the transfer characteristics at different $V_{ds}$ ranging from 0.025 V to 1 V which exhibits a typical n-type behavior. The output curves shown in the Figure 3 (c) present the saturation properties of the monolayer MoS$_2$ FET, in which the ohmic contact characteristics can be observed at lower $V_{ds}$. Compared with the non-ohmic contact in the MoS$_2$ FET without the SiO$_2$ protective layer, it can be obviously claimed that the performance of the MoS$_2$ FET can be largely improved by applying a SiO$_2$ protective layer.
**WSe₂ FETs based on LPCVD process**

**A. Introduction**

In this work, large-scale growth of high-quality WSe₂ atomic layers directly on SiO₂/Si substrates using a low pressure chemical vapor deposition (LPCVD) method was reported. The influence of growth temperature, carrier gas flow rate and tube pressure was investigated, which affects the sizes, shapes and the thickness of as-grown WSe₂ flakes. By applying a pre-annealing step, the quality of WSe₂ flakes improve a lot which show the lateral size up to 30 μm and monolayer thin film area of 0.25 mm². After that, raman spectrum, microphotoluminescence and auger electron spectroscopy (AES) were performed to characterize the as-grown WSe₂ flakes. Finally, p-type WSe₂ field-effect transistors were fabricated using the WSe₂ flakes which exhibit excellent electrical properties with carrier mobility of ~ 64 cm² · V⁻¹ · s⁻¹ and current on/off ratio over 10⁵. This work opens a new way for the customized low-dimensional non-graphene FET fabrication.

**B. Larger scale single crystal WSe₂ growth by LPCVD process**

The LPCVD process was performed in a homemade tube furnace with a vacuum pump and pressure meter. After a specific annealing process (see Ref.3 for details), WSe₂ powder (0.2 g) was placed in a quartz boat at the center of a quartz tube, and the clean SiO₂/Si substrates were used as the growth substrate at the downstream with variable temperature. High-purity Argon gas with a designed flow rate was continuously supplied as the carrier gas and the pressure in the tube was pumped down to 10 Pa during the whole growth process. The tube furnace was heated up to 1060 °C in 30 mins and maintained 30 mins for growth. Finally, the whole system was naturally cooled down to ambient temperature.

The as-grown WSe₂ flakes was observed by optical microscope (OM) shown in Figure 4 to Figure 6. Figure 4 shows the influence of temperature on WSe₂ growth, demonstrating larger area flakes begin to appear and merge together with temperature decreasing. However, when the temperature became lower, WSe₂ flakes disappeared and WSe₂ nanoflowers began to form. Figure 5 shows the WSe₂ growth at different tube pressures, indicating suitable lower tube pressure can increase the WSe₂ film size. Figure 6 shows the optical images of the as-grown
WSe$_2$ flakes under an Ar flow rate of 200 SCCM and the layer number and the domain size of WSe$_2$ are increased with the increasing of the gas flow rate. Besides, Raman spectrum, microphotoluminescence and auger electron spectroscopy (AES) were performed to characterize the as-grown WSe$_2$ flakes in Figure 7, which confirm the monolayer, uniformity and chemical composition of the WSe$_2$ flakes.

Figure 4. WSe$_2$ growth with temperatures varying from 850$^\circ$C to 700$^\circ$C. Optical microscope images of WSe$_2$ samples grown at different temperatures under a designed flow rate and vacuum degree (100 SCCM, 200 Pa) for 30 min: (a) 850$^\circ$C, WSe$_2$ particles; (b) 800$^\circ$C, WSe$_2$ flakes; (c) 780$^\circ$C, larger WSe$_2$ flakes; (d) 760$^\circ$C, larger WSe$_2$ flakes; (e) 750$^\circ$C, WSe$_2$ film and (f) 700$^\circ$C, WSe$_2$ nanoflowers. All the scale bars are 20 $\mu$m.

Figure 5. Optical images of WSe$_2$ with different growth pressures: (a) 280 Pa, (b) 180 Pa and (c) 70 Pa. All the scale bars are 20 $\mu$m and the temperature used for the pressure dependency study is 765$^\circ$C.
Figure 6. Optical microscope images of large WSe$_2$ samples grown under an argon flow rate of 200 SCCM for 30 min. From (a) to (d), the temperature decreases from 850°C to 750°C. All the scale bars are 20 μm.

C. Electrical characterization of the monolayer back-gated WSe$_2$ FET

The as-grown WSe$_2$ flakes were subsequently used to fabricate back-gated FETs by electronic beam lithography. 5 nm Ti and 25 nm Au were evaporated on the WSe$_2$ flakes to make the source and drain. Figure 8 shows the transfer curves and output curves of the WSe$_2$ FETs. The typical $I_{DS}$-$V_{GS}$ curve in Figure 8 (a) indicates a p-type behavior while the linearity of $I_{DS}$-$V_{DS}$ curves demonstrates ohmic contacts were formed at the source and drain electrodes. The charge mobility and on/off current ratios of the FETs were $\sim 64$ cm$^2$ · V$^{-1}$ · s$^{-1}$ and $10^5$ respectively, which are comparable to the reported results based on exfoliated WSe$_2$. [3]
A. Introduction

An as-prepared BP FET was fabricated using a simple dry transfer method to minimize polymer residues and avoid the liquid immersion process compared with conventional material transfer process. As a result, BP with little degradation was achieved while the BP FET exhibited excellent electrical properties with a relatively high on/off ratio of $10^4$ and a high hole mobility exceeding 380 cm$^2$/(V s). Besides, due to the degradation and doping effect, BP shows a time-dependent electrical property indicating the declining and recovering process. Finally, it was demonstrated that the degradation and large-scale hysteresis of BP FET could be modified by covering a thin Al$_2$O$_3$ layer.

B. BP characterization and device fabrication

The details of BP using a simple dry transfer method were referred in Ref.4 [4]. The AFM image in Figure 9 (a) shows the uniformity of the dry-transferred BP with a thickness of only 5 nm, demonstrating the transfer technique performed well. However, the three obvious peaks (A$_{1g}$, B$_{2g}$, and A$_{2g}$) of the Raman spectrum in Figure 9 (b) indicate that the dry transferred BP is not monolayer. [6]

The all-dry transfer process for fabricating BP FET is shown in Figure 10. Firstly, thin-layer BP was exfoliated onto a transparent poly (vinyl chloride) (PVC) film and adhered the film to the micromanipulation platform. After that, the few-layer BP was transferred onto the stripe-shaped electrodes on the Si/SiO$_2$ substrate by pressing the PVC film down. Finally, lift up the film and the target BP was left on the electrodes to achieve a BP FET with bottom electrodes. It is worth noting that the air exposure time should be limited to 10 min during the fabrication and an annealing process is necessary to improve the contact between electrodes and BP, in which the sample is heated at 200 °C in an argon environment for 20 min.
C. Electrical characterization of BP FET

The electrical property of BP FET was measured in ambient atmosphere shown in Figure 11. The on-state current reached up at 0.01 V drain bias and the on/off ratio exceeded $10^4$. The hole mobility was calculated up to $380 \text{ cm}^2/(V \cdot \text{s})$, which is comparable to those in other related literatures where BP FET was fabricated in a glove box or measured in vacuum. [5] Figure 11 (b) shows the output characteristic of BP FETs [6]. For a negative back gate voltage, the current tends to saturate at a high drain bias because of pinch-off. However, the drain current exhibited Schottky behavior when the back gate voltage was more than 0 V, which was demonstrated in other work as well. [5]

Figure 12 (a) shows the transfer curve measured under different times, indicating that the electrical conduction of BP was quickly changed from declining to recovering. After depositing a Al$_2$O$_3$ protection layer, the transfer curves of BP FET with initial state and 150 min exposure to ambient atmosphere were shown in Figure 12 (b) and (c). The limited changes in the two curves demonstrate the excellent protective function of Al$_2$O$_3$ layer. This research has great significance to the fundamental researches and applications of BP. [4]
CONCLUSIONS

Three works related to non-graphene 2D materials FETs are presented in this paper. The inserted SiO2 protective layer enhances the carrier mobility and the source-drain current of MoS2 FETs. And larger scale single crystal WSe2 growth by LPCVD process shows the potential to fabricate wafer-scale logic circuits. Moreover, BP FET based on a simple dry transfer method provides a process to improve the performance of the device based on unstable materials. These novel non-graphene based FETs processes inspire new design of basic logic device and their application in electronic systems.
