Promoting coronavirus disease 2019 (COVID-19) vaccination: Do we need to reframe how we present risk?

Michelle Doll MD, MPH1, Jeanine P. D. Guidry PhD2, Rachel Pryor RN, MPH3, Arthur L. Kellermann MD, MPH1 and Michael P. Stevens MD, MPH1

To the Editor—Although impressive progress has been made in vaccinating the US population against coronavirus disease 2019 (COVID-19), the country has not yet reached the level of uptake needed to assure the added benefit of “herd immunity.”1 Equally if not more concerning, substantial subgroups of the population remain skeptical if not overtly resistant to vaccination. To convince as many of these individuals as possible to change their mind, it is imperative that we communicate the benefits of vaccination in more meaningful ways.

Recently we reported how Virginia Commonwealth University Medical Center in Richmond swiftly contained an outbreak of employee infections that coincided with the “third wave” of COVID-19 that hit Virginia between December 2020 to January 2021.1 During a single week (December 13–19), 134 of 13,346 employees, or ~1% of our entire workforce, became infected with severe acute respiratory coronavirus virus 2 (SARS-CoV-2). Fortunately, we received our first doses of vaccine that same week and began vaccinating employees on December 16. The campaign that followed, along with a bundle of intensified infection-prevention measures, produced a 10-fold reduction in healthcare worker (HCW) infections (down to 0.1%) by January 31. Based on our local experience, we calculated that getting vaccinated against COVID-19 reduces a VCU Health employee’s odds of getting infected by 98%.2

A recent study from Israel reported the real-world effectiveness of the Pfizer-BioNTech mRNA vaccine BNT162b2. The incidence rate of SARS-CoV-2 per 100,000 person days was 91.5 in unvaccinated people versus 3.1 in fully vaccinated people—an effectiveness rate of 95.3 percent.3 In other words, unvaccinated people were 29.5 times more likely to become infected than those who were vaccinated.

Rather than focus on the risks of vaccination, which is tiny by comparison, the public would be better served by focusing on the far larger and more severe risk incurred by those who forego or decline repeated opportunities to be vaccinated.

If VCU Health data are representative of the general public, the risk that an unvaccinated adult will become infected with the virus that has killed >600,000 Americans and >3.4 million people worldwide, is ~28 times higher than those who accept vaccination. This way of framing risk may be of value to infection prevention specialists involved in COVID-19 vaccine messaging campaigns.
