#### Abstract

Let $T$ be a bounded operator on a complex Banach space $X$. Let $V$ be an open subset of the complex plane. We give a condition sufficient for the mapping $f(z) \mapsto(T-z) f(z)$ to have closed range in the Fréchet space $H(V, X)$ of analytic $X$ valued functions on $V$. Moreover, we show that there is a largest open set $U$ for which the map $f(z) \mapsto(T-z) f(z)$ has closed range in $H(V, X)$ for all $V \subseteq U$. Finally, we establish analogous results in the setting of the weak-* topology on $H\left(V, X^{*}\right)$.

2000 Mathematics Subject Classification. 47A11.

Introduction. Let $X$ be a complex Banach space and denote by $B(X)$ the algebra of bounded linear operators on $X$. For $T \in B(X)$, let $\sigma(T)$ denote the spectrum of $T$, and denote by Lat $(T)$ the collection of closed $T$-invariant subspaces of $X$. If $M \in \operatorname{Lat}(T)$, we write the restriction of $T$ to $M$ as $\left.T\right|_{M}$.

A basic notion in local spectral theory is that of decomposability. Given an open subset $U$ of the complex plane $\mathbb{C}, T \in B(X)$ is said to be decomposable on $U$ provided that for any open cover $\left\{V_{1}, \ldots, V_{n}\right\}$ of $\mathbb{C}$ with $\mathbb{C} \backslash U \subset V_{1}$, there exists $\left\{X_{1}, \ldots, X_{n}\right\} \subset$ Lat ( $T$ ) such that $X=X_{1}+\cdots+X_{n}$ and $\sigma\left(\left.T\right|_{X_{k}}\right) \subset V_{k}$ for each $k, 1 \leq k \leq n$; see [2], [5], [8], [11], and [12]. That for each $T \in B(X)$ there exists a largest open set $U$ on which $T$ is decomposable was first shown by Nagy, [11].

An alternative characterization of decomposability may be given in terms of a property introduced by E. Bishop, [3]. For an open subset $V$ of $\mathbb{C}$, let $H(V, X)$ denote the space of all analytic $X$-valued functions on $V$. Then $H(V, X)$ is a Frechet space with generating semi-norms given by $p_{K}(f):=\sup \{\|f(\lambda)\|: \lambda \in K\}$, where $K$ runs through the compact subsets of $V$. Every operator $T \in B(X)$ induces a continuous linear mapping $T_{V}$ on $H(V, X)$, defined by $T_{V} f(\lambda):=(T-\lambda) f(\lambda)$ for all $f \in H(V, X)$ and $\lambda \in V$. An operator $T$ is said to possess Bishop's property $(\beta)$ on an open set $U \subset \mathbb{C}$ if for each open subset $V$ of $U$, the operator $T_{V}$ is injective with range $\operatorname{ran} T_{V}$

[^0]closed in $H(V, X)$; see [6, Prop. 1.2.6]. Clearly there exists a largest open set $\rho_{\beta}(T)$ on which $T$ has property $(\beta)$.

Fundamental work by Albrecht and Eschmeier established that an operator $T \in$ $B(X)$ has property $(\beta)$ on $U$ precisely when there exists an operator $S \in B(Y)$ such that $S$ is decomposable on $U, X \in \operatorname{Lat}(S)$ and $T=\left.S\right|_{X}$, [2, Theorem 10]. Moreover, [2, Theorems 8 and 21], $T$ is decomposable on $U$ if and only if $T$ and its adjoint $T^{*}$ share property $(\beta)$ on $U$. Thus Nagy's largest open set on which $T$ is decomposable is the set $\rho_{\beta}(T) \cap \rho_{\beta}\left(T^{*}\right)$.

An operator $T \in B(X)$ is said to have the single-valued extension property (SVEP) at a point $\lambda \in \mathbb{C}$ provided that, for every open disc $V$ centered at $\lambda$, the mapping $T_{V}$ is injective on $H(V, X)$. If $U \subset \mathbb{C}$ is open, then $T$ is said to have SVEP on $U$ if $T$ has SVEP at every $\lambda \in U$, equivalently, if $T_{V}$ is injective for each open set $V \subseteq U$. Let $\rho_{\text {SVEP }}(T)$ denote the largest open set on which $T$ has SVEP.

Recently, M. Neumann, V. Miller and the first author of the current paper showed, [9, Theorem 2.5], that $T_{V}$ has closed range in $H(V, X)$ for every open subset $V$ of the "Kato-type" resolvent set of $T$, an open set that contains the semi-Fredholm region of $T$, thus extending a result of Eschmeier, [5]. Following Neumann, we say that an operator has the closed range property $(\mathrm{CR})$ on an open set $U \subset \mathbb{C}$ provided $\operatorname{ran}\left(T_{V}\right)$ is closed in $H(V, X)$ for every open subset $V$ of $U$. Thus $T$ has property $(\beta)$ on $U$ if and only if $T$ has both SVEP and (CR) on $U$.

In this note, we give a more general condition that suffices for $T \in B(X)$ to have (CR) on an open set $U$ and prove that there is in fact a largest open set $\rho_{\mathrm{CR}}(T)$ on which $T$ has the closed range property. Thus $\rho_{\beta}(T)=\rho_{\mathrm{SVEP}}(T) \cap \rho_{\mathrm{CR}}(T)$. In the last section we establish corresponding results in the setting of the weak-* topology on $H\left(V, X^{*}\right)$.

Main results. We denote the kernel of $T \in B(X)$ by $\operatorname{ker}(T)$ and define $N^{\infty}(T):=$ $\bigcup_{n \geq 0} \operatorname{ker}\left(T^{n}\right)$ and $R^{\infty}(T):=\bigcup_{n \geq 0} \operatorname{ran}\left(T^{n}\right)$. If $T \in B(X)$ is such that $\operatorname{ran}(T)$ is closed and $N^{\infty}(T) \subseteq R^{\infty}(T)$, then $T$ is said to be a Kato operator. A systematic exposition of this class, also referred to as semi-regular operators, may be found in [10, Section II.12]; also see [1, Section 1.2] and [6, Section 3.1]. In particular, an equivalent condition may be given in terms of the reduced minimum modulus function: for $S \in B(X)$, define $\gamma(S):=\inf \{\|S x\|: \operatorname{dist}(x, \operatorname{ker}(S))=1\}$. Then an operator $T$ is Kato if and only if $\gamma(T)>0$ and the mapping $z \rightarrow \gamma(T-z)$ is continuous at $0,[\mathbf{1 0}$, II. 12 Theorem 2]. Denote by $\sigma_{K}(T)$ the set of all $\lambda \in \mathbb{C}$ such that $T-\lambda$ is not Kato. Then $\sigma_{K}(T)$ is a nonempty compact set, $z \mapsto R^{\infty}(T-z)$ is constant on each component of $\rho_{K}(T):=$ $\mathbb{C} \backslash \sigma_{K}(T), R^{\infty}(T-\lambda)$ is closed and $(T-\lambda) R^{\infty}(T-\lambda)=R^{\infty}(T-\lambda)$ for each $\lambda \in$ $\rho_{K}(T),\left[\mathbf{1 0}\right.$, II.12, Theorem 15 and Cor. 19]. Moreover, if $G$ is a component of $\rho_{K}(T)$ and $S \subset G$ has an accumulation point in $G$, then $\bigcap_{z \in S} \operatorname{ran}(T-z)=R^{\infty}(T-\lambda)$ for each $\lambda \in G,[6,3.1 .11]$.

For each closed subset $F$ of $\mathbb{C}$, define the "glocal" analytic spectral subspace $\mathfrak{X}_{T}(F):=\left\{x \in X: x \in \operatorname{ran} T_{\mathbb{C} \backslash F}\right\}$. These spaces are $T$-invariant, but generally not closed. If $M \in \operatorname{Lat}(T)$ and $V \subset \mathbb{C}$ is such that $(T-z) M=M$ for all $z \in V$, then $M \subset \mathfrak{X}_{T}(\mathbb{C} \backslash V)$ by a theorem of Leiterer, [6, Theorem 3.2.1]. It follows from above that if $G$ is a component of $\rho_{K}(T)$ and $V \subset G$ is open, then $\mathfrak{X}_{T}(\mathbb{C} \backslash V)=R^{\infty}(T-\lambda)$ for all $\lambda \in G$; in particular, $\mathfrak{X}_{T}(\mathbb{C} \backslash V)$ is closed. Also, it is easily seen that if $T$ has (CR) on an open set $U$, then $\mathfrak{X}_{T}(\mathbb{C} \backslash V)$ is closed for every open $V \subset U$.

A consequence of Theorem 5 below is that the converse holds under the additional assumption that $\operatorname{ran}(T-z)$ is closed for all but countably many $z \in V$. Some additional
assumption beyond closeness of the glocal spectral subspaces is seen to be necessary for (CR) by the facts that, on one hand, $T$ has property $(\beta)$ on all of $\mathbb{C}$ precisely when $T$ has (CR) on $\mathbb{C}$, [6, Prop. 3.3.5], while on the other hand, there is an operator $T \in B(X)$ without property $(\beta)$ but for which $\mathfrak{X}_{T}(F)$ is closed for all closed $F \subset \mathbb{C}$, [7].

If $(X, d)$ is a metric space, let $B(x, r)$ denote the open ball in $X$ with radius $r>0$ and center $x \in X$.

Lemma 1. Let $T \in B(X)$ and let $V$ be an open subset of $\mathbb{C}$. Let $\left(D_{i}\right)_{i \in A}$ be a cover of $V$ consisting of simply connected open sets $D_{i}$ such that $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$ is closed for each $i \in A$ and $D_{i} \backslash D_{j} \neq \emptyset$ if $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right) \neq \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$.

Let $M=\bigcap_{i \in A} \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$. Then $M$ is closed, $T M \subset M$ and
(i) if $x \in M$ and $g_{j} \in H\left(D_{j}, X\right)$ are such that $T_{D_{j}} g_{j}=x$, then $g_{j}\left(D_{j}\right) \subset M$;
(ii) $\operatorname{ker} T_{D_{j}} \subset H\left(D_{j}, M\right)$;
(iii) $(T-z) M=M$ for all $z \in V$;
(iv) if $\widetilde{T}: X / M \rightarrow X / M$ is the quotient map induced by $T$ then $\widetilde{T}_{D_{j}}$ is injective on $H\left(D_{j}, X / M\right)$.

Proof. Clearly $M$ is a closed subspace of $X$ and $T M \subset M$.
(i) Let $x \in M$ and $g_{j} \in H\left(D_{j}, X\right)$ be such that $T_{D_{j}} g_{j}=x$.

We show first that $g_{j}\left(D_{j}\right) \subset \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$. Let $z \in D_{j}$, and define $h_{j}: D_{j} \rightarrow X$ by $h_{j}(\omega)=$ $\left(g_{j}(\omega)-g_{j}(z)\right) /(\omega-z)$ if $\omega \in D_{j} \backslash\{z\}$ and $h_{j}(z)=g_{j}^{\prime}(z)$. Then $h_{j} \in H\left(D_{j}, X\right)$ and if $\omega \neq$ $z$, then

$$
(T-\omega) h_{j}(\omega)=\frac{1}{\omega-z}\left(x-((T-z)+(z-\omega)) g_{j}(z)\right)=g_{j}(z) .
$$

By continuity, $(T-z) h_{j}(z)=g_{j}(z)$ as well. Hence $g_{j}(z) \in \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$ and so $g_{j}\left(D_{j}\right) \subset$ $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$.

If $i \in A$ is such that $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right) \neq \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$, let $g_{i} \in H\left(D_{i}, X\right)$ be such that $T_{D_{i}} g_{i}=x$, let $z \in D_{j} \backslash D_{i}$ and define $h_{i}: D_{i} \rightarrow X$ by $h_{i}(\omega)=\left(g_{i}(\omega)-g_{j}(z)\right) /(\omega-z)$. Then $h_{i} \in H\left(D_{i}, X\right)$ and again

$$
\begin{aligned}
(T-\omega) h_{i}(\omega) & =\frac{1}{\omega-z}\left((T-\omega) g_{i}(\omega)-((T-z)+(z-\omega)) g_{j}(z)\right) \\
& =\frac{1}{\omega-z}\left(x-x+(\omega-z) g_{j}(z)\right)=g_{j}(z)
\end{aligned}
$$

Thus $g_{j}(z) \in \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$ and $g_{j}\left(D_{j} \backslash D_{i}\right) \subset \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$.
Since the sets $D_{i}$ and $D_{j}$ are open, simply connected and $D_{j} \backslash D_{i} \neq \emptyset$, it is easy to see that $D_{j} \backslash D_{i}$ contains an accumulation point. Indeed, let $z_{0} \in D_{j} \backslash D_{i}$. If $z_{0} \notin \overline{D_{i}}$ then there is an open neighborhood of $z_{0}$ contained in $D_{j} \backslash \overline{D_{i}}$. If $z_{0} \in \partial D_{i}$, then there is a sequence $\left(z_{n}\right) \subset D_{j} \backslash D_{i}$ such that $z_{n} \rightarrow z_{0}$.

Since $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$ is closed and $g_{j}\left(D_{j} \backslash D_{i}\right) \subset \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$, it follows that $g_{j}: D_{j} \rightarrow$ $\mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{i}\right)$.

This proves (i).
(ii) is an immediate consequence of (i).
(iii) Let $z \in D_{j}$ and $x \in M \subset \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{j}\right)$. There is a function $g_{j}: D_{j} \rightarrow X$ such that $T_{D_{j}} g_{j}=x$. By (i), $g_{j}(z) \in M$ and so $x=(T-z) g_{j}(z) \in(T-z) M$.
(iv) If $\pi: X \rightarrow X / M$ is the canonical projection, then Gleason's theorem implies that the sequence $0 \rightarrow H(\Omega, M) \rightarrow H(\Omega, X) \xrightarrow{\pi} H(\Omega, X / M) \rightarrow 0$ is exact, [6, Prop. 2.1.5]. Thus, if $\widetilde{T}_{D_{j}} h=0$ for some $h \in H\left(D_{j}, X / M\right)$, then there exists
$f \in H\left(D_{j}, X\right)$ such that $h=\tilde{f}$, where $\tilde{f}=\pi \circ f$. Clearly $T_{D_{j}} f \in H\left(D_{j}, M\right)$ and (iii) together with Leiterer's theorem implies that there exists $g \in H\left(D_{j}, M\right)$ such that $T_{D_{j}} f=T_{D_{j}} g$. Thus $f-g \in \operatorname{ker} T_{D_{j}} \subset H\left(D_{j}, M\right)$ by (ii). Consequently, $f \in H\left(D_{j}, M\right)$ and therefore, $h=\tilde{f}=0$.

Lemma 2. Let $V_{1}, V_{2}$ be open subsets of $\mathbb{C}$ and suppose that $\Omega$ is an open subset of $V_{1} \cup V_{2}$. Then there exist open sets $\Omega_{1}, \Omega_{2}$ so that $\Omega_{j} \subset V_{j}, \Omega=\Omega_{1} \cup \Omega_{2}$ and an open cover $\mathcal{U}$ of $\Omega$ such that
(i) each $D \in \mathcal{U}$ is a simply connected subset of either $V_{1}$ or $V_{2}$;
(ii) if $G$ is a component of $\Omega_{1} \cap \Omega_{2}$, then there is a $D \in \mathcal{U}$ such that $D \subset G$;
(iii) $D \backslash D^{\prime} \neq \emptyset$ whenever $D, D^{\prime} \in \mathcal{U}$ are distinct.

Proof. Let $U_{j}=V_{j} \cap \Omega$ for $j=1,2$ and define $\Omega_{1}$ to be the union of all components $G$ of $U_{1}$ such that $G \backslash U_{2} \neq \emptyset$, and $\Omega_{2}$ the union of components $H$ of $U_{2}$ such that $H \backslash \Omega_{1} \neq \emptyset$. Then, each $\Omega_{j}$ is open, and every component of $\Omega_{j}$ is a component of $U_{j}$. We may assume that each $\Omega_{j}$ is nonempty. Clearly, $\Omega=\Omega_{1} \cup U_{2}$, and if $H$ is a component of $U_{2}$, then either $H \subset \Omega_{1}$ or $H \subset \Omega_{2}$. Thus $\Omega=\Omega_{1} \cup \Omega_{2}$.

Let $G_{1}, G_{2}, \ldots$ be the components of $\Omega_{1} \cap \Omega_{2}$. We note $\partial G_{n} \cap \Omega_{j} \neq \emptyset$ for each $n \in \mathbb{N}$ and $j=1,2$. Indeed, suppose to the contrary that $\partial G_{n} \cap \Omega_{1}=\emptyset$. Let $M_{j}$ be the component of $\Omega_{j}$ containing $G_{n}$. Then $M_{1}=G_{n} \cup\left(M_{1} \backslash \overline{G_{n}}\right)$, where $G_{n} \neq \emptyset$ and where $M_{1} \backslash \overline{G_{n}}=M_{1} \backslash G_{n} \supset M_{1} \backslash M_{2} \neq \emptyset$, contradicting the fact that $M_{1}$ is connected. That $\partial G_{n} \cap \Omega_{2} \neq \emptyset$ follows similarly.

Choose $\lambda_{n} \in \partial G_{n} \cap \Omega_{1}$ and $\mu_{n} \in \partial G_{n} \cap \Omega_{2}$. Then $\lambda_{n} \notin \Omega_{2}$ and $\mu_{n} \notin \Omega_{1}$. Select $\lambda_{n}^{\prime}, \mu_{n}^{\prime} \in G_{n}$ so that $\left|\lambda_{n}-\lambda_{n}^{\prime}\right|<2^{-n}$ and $\left|\mu_{n}-\mu_{n}^{\prime}\right|<2^{-n}$. If we construct a piecewise linear path in $G_{n}$ connecting $\lambda_{n}^{\prime}$ and $\mu_{n}^{\prime}$, then, taking such a path with minimal number of segments, we obtain a path $\gamma_{n}$ between $\lambda_{n}^{\prime}$ and $\mu_{n}^{\prime}$ that does not intersect itself. Clearly it is possible to find a simply connected open set $D_{n}$ so that $\gamma_{n} \subset D_{n} \subset G_{n}$.

Let $D=\bigcup_{n} D_{n}$ and suppose that $z \in \Omega_{1} \backslash D$. We claim that there is a $\delta(z)>$ 0 such that $B(z, \delta(z)) \subset \Omega_{1}$ and $B(z, \delta(z)) \cap\left\{\mu_{1}^{\prime}, \mu_{2}^{\prime}, \ldots\right\}=\emptyset$. To this end, choose $\varepsilon(z)>0$ so that $B(z, \varepsilon(z)) \subset \Omega_{1}$, and let $n_{0}$ be such that $2^{-n_{0}}<\varepsilon(z) / 2$. Now, let $\delta(z)=\min \left\{\varepsilon(z) / 2,\left|z-\mu_{1}^{\prime}\right|, \ldots,\left|z-\mu_{n_{0}-1}^{\prime}\right|\right\}$. Then $\mu_{n}^{\prime} \notin B(z, \delta(z))$ if $n<n_{0}$, and if $n \geq n_{0}$, then $\mu_{n} \notin \Omega_{1}$ implies that $\left|z-\mu_{n}^{\prime}\right| \geq\left|z-\mu_{n}\right|-\left|\mu_{n}-\mu_{n}^{\prime}\right| \geq \varepsilon(z)-2^{-n_{0}}>\delta(z)$, as required. Similarly, if $z \in \Omega_{2} \backslash \Omega_{1}$, then there is a $\delta(z)>0$ such that $B(z, \delta(z)) \subset \Omega_{2}$ and $B(z, \delta(z)) \cap\left\{\lambda_{1}^{\prime}, \lambda_{2}^{\prime}, \ldots\right\}=\emptyset$.

We define a sequence of (possibly empty) collections of open balls recursively: for each $k \geq 1$, let $\mathcal{U}_{k}:=\left\{B\left(z, 2^{-j}\right): \delta(z) \geq 2^{-k}\right.$ and $\left.B\left(z, 2^{-k}\right) \not \subset V_{k-1}\right\}$, where $V_{0}=\emptyset$ and $V_{j}:=\bigcup_{\ell \leq j} \bigcup_{B \in \mathcal{U}_{\ell}} B$ for all $j \geq 1$. If $z \in \Omega \backslash D$, then there is a least $m$ so that $\delta(z) \geq 2^{-m}$, and so either $B\left(z, 2^{-m}\right) \subset V_{m-1}$ or $B\left(z, 2^{-m}\right) \in \mathcal{U}_{m}$. Thus $z \in V_{m}$ in either case. It follows that $\Omega \backslash D=\bigcup_{k=1}^{\infty} V_{k}=\bigcup_{\ell=1}^{\infty} \bigcup_{B \in \mathcal{U}_{\ell}} B$, and consequently $\mathcal{U}:=\left\{D_{n}\right\}_{n} \cup \bigcup_{\ell=1}^{\infty} \mathcal{U}_{\ell}$ is an open cover of $\Omega$ satisfying the desired conditions.

Lemma 3. Let $V_{1}, V_{2}$ be open subsets of $\mathbb{C}$. If $T \in B(X)$ has $(C R)$ on each $V_{j} \quad(j=$ $1,2)$, then $T$ has $(C R)$ on $V_{1} \cup V_{2}$.

Proof. Let $\Omega \subset V_{1} \cup V_{2}$ be an open set. To show that $T_{\Omega}$ has closed range, let $\Omega_{1}$, $\Omega_{2}$ and $\mathcal{U}$ be as in the previous lemma, and let $f \in \overline{\operatorname{ran} T_{\Omega}}$. Since $T$ has (CR) on each $\Omega_{j}, \mathfrak{X}_{T}(\mathbb{C} \backslash D)$ is closed for each $D \in \mathcal{U}$ and there are $g_{j} \in H\left(\Omega_{j}, X\right)$ such that $\left.f\right|_{\Omega_{j}}=$ $T_{\Omega_{j}} g_{j}$ for $j=1$, 2 . Define $M:=\bigcap_{D \in \mathcal{U}} \mathfrak{X}_{T}(\mathbb{C} \backslash D)$. We have $T_{\Omega_{1} \cap \Omega_{2}}\left(g_{1}-g_{2}\right)=0$, and so $\left(g_{1}-g_{2}\right)\left(\Omega_{1} \cap \Omega_{2}\right) \subset M$ by Lemma 1 (ii). Thus $\left.\widetilde{g_{1}}\right|_{\Omega_{1} \cap \Omega_{2}}=\left.\widetilde{g_{2}}\right|_{\Omega_{1} \cap \Omega_{2}}$ and we can define $h \in H(\Omega, X / M)$ by $h(z)=\widetilde{g}_{j}(z)$ for $z \in \Omega_{j}$. We have $\tilde{f}=\widetilde{T}_{\Omega} h$ and, again by Gleason's
theorem, there exists $g \in H(\Omega, X)$ such that $h=\tilde{g}$. Then $f-T_{\Omega} g \in H(\Omega, M)$ and so Lemma 1 (iii) and Leiterer's theorem together imply that $f-T_{\Omega} g=T_{\Omega} k$ for some $k \in H(\Omega, M)$. Hence $f=T_{\Omega}(g+k) \in \operatorname{ran} T_{\Omega}$.

Theorem 4. Let $T \in B(X)$. Then there is a largest open set $\rho_{C R}(T)$ on which $T$ has (CR).

Proof. Let $\mathcal{W}$ be the family of all open subsets $V \subset \mathbb{C}$ such that $T$ has (CR) on $V$. We show that $T$ has (CR) on the union $W=\bigcup \mathcal{W}$, which is obviously the largest open set on which $T$ has (CR).

Let $\Omega \subset W$ be a nonempty open subset. We show that $T_{\Omega}$ has closed range. For each $z \in \Omega$ choose $0<\delta(z)<\operatorname{dist}(z, \partial \Omega)$ so that $T$ has (CR) on $B(z, \delta(z))$. As in the proof of Lemma 2, define $\mathcal{U}_{k}:=\left\{B\left(z, 2^{-k}\right): \delta(z) \geq 2^{-k}\right.$ and $\left.B\left(z, 2^{-k}\right) \not \subset V_{k-1}\right\}$, where $V_{j}:=\bigcup_{\ell \leq j} \bigcup_{B \in \mathcal{U}_{\ell}} B$ and $V_{0}=\emptyset$. Then, again as in Lemma $2, \Omega=\bigcup_{m \geq 1} V_{m}$, and so $\mathcal{U}^{\prime}:=\bigcup_{m=1}^{\infty} \mathcal{U}_{m}$ is a collection of open balls covering $\Omega$ such that $T$ has (CR) on each ball $D \in \mathcal{U}^{\prime}$ and also such that $D \neq D^{\prime}$ in $\mathcal{U}^{\prime}$ implies $D \backslash D^{\prime} \neq \emptyset$. Let $\mathcal{U}=\left(D_{k}\right)_{k \in \mathbb{N}}$ be a countable subcover of $\mathcal{U}^{\prime}$ and define $\Omega_{n}=\bigcup_{k \leq n} D_{k}$. By Lemma 3, $T$ has (CR) on each $\Omega_{n}$.

Let $M=\bigcap_{n} \mathfrak{X}_{T}\left(\mathbb{C} \backslash D_{n}\right)$. By Lemma $1, M$ is a closed subspace of $X, T M \subset M$ and $(T-z) M=M$ for all $z \in \Omega$. Denote by $\widetilde{T}: X / M \rightarrow X / M$ the operator induced by $T$ and by $\pi: X \rightarrow X / M$ the canonical projection.

Let $f \in \overline{\operatorname{ran} T_{\Omega}}$. Then for each $n$ there exists $g_{n} \in H\left(\Omega_{n}, X\right)$ such that $\left.f\right|_{\Omega_{n}}=T_{\Omega_{n}} g_{n}$. If $n \geq 2$, then $T_{\Omega_{n-1}}\left(g_{n} \mid \Omega_{n-1}-g_{n-1}\right)=0$ and so, by Lemma 1 (ii), $\left.g_{n}\right|_{\Omega_{n-1}}-g_{n-1}$ : $\Omega_{n-1} \rightarrow M$, i.e., $\left.\widetilde{g}_{n}\right|_{\Omega_{n-1}}=\widetilde{g}_{n-1}$ in $H\left(\Omega_{n-1}, X / M\right)$.

Define $h: \Omega \rightarrow X / M$ by $\left.h\right|_{\Omega_{n}}=\widetilde{g}_{n}$. Then $h$ is well-defined and analytic on $\Omega$. Also, $\tilde{f}=\widetilde{T}_{\Omega} h$ in $H(\Omega, X / M)$. By Gleason's theorem, there exists $g \in H(\Omega, X)$ such that $\tilde{g}=h$ and therefore, $\pi\left(f-T_{\Omega} g\right)=0$. Exactness implies that $f-T_{\Omega} g \in H(\Omega, M)$, and so it again follows from Lemma 1 (iii) and Leiterer's theorem that there is a $k \in H(\Omega, M)$ such that $f-T_{\Omega} g=T_{\Omega} k$, i.e., $f=T_{\Omega}(g+k) \in \operatorname{ran} T_{\Omega}$.

Theorem 5. Let $T \in B(X)$ and let $V \subset \mathbb{C}$ be an open set. Suppose that the set $\{z \in V: \operatorname{ran}(T-z)$ is not closed $\}$ is countable and that, for all $z \in V$, there is an $r_{0}>0$ for which $\mathfrak{X}_{T}(\mathbb{C} \backslash B(z, r))$ is closed for all $r \in\left(0, r_{0}\right)$. Then $T$ has $(C R)$ on $V$.

Proof. Since the conditions of the theorem are inherited by every open subset $U$ of $V$, it suffices to show that $T_{V}$ has closed range in $H(V, X)$. Moreover, because the set $\{z \in \mathbb{C}: \operatorname{ran}(T-z)$ is closed and $T-z$ is not Kato $\}$ is countable by [10, II. 12 Theorem 13], it follows that $E:=V \cap \sigma_{K}(T)$ is countable; let $E=\left\{\lambda_{n}: n=1,2, \ldots\right\}$ be an enumeration of $E$ (possibly finite). Note that, while $E$ need not be discrete, the set $V \backslash E=V \cap \rho_{K}(T)$ is open.

We construct a sequence $\left(B_{j}\right)$ of mutually disjoint open discs such that $E \subset \bigcup_{j} B_{j}$, $\overline{B_{j}} \subset V$ and $\mathfrak{X}_{T}\left(\mathbb{C} \backslash B_{j}\right)$ is closed for each $j$. Indeed, choose $r_{1}>0$ such that $\overline{B\left(\lambda_{1}, r_{1}\right)} \subset$ $V, \mathfrak{X}_{T}\left(\mathbb{C} \backslash B\left(\lambda_{1}, r_{1}\right)\right)$ is closed, and $\left|\lambda_{j}-\lambda_{1}\right| \neq r_{1} \quad(j \geq 2)$. Set $B_{1}=B\left(\lambda_{1}, r_{1}\right)$. Let $k$ be the smallest index such that $\lambda_{k} \notin B_{1}$ and find $r_{2}>0$ such that $B_{2}:=B\left(\lambda_{k}, r_{2}\right)$ satisfies $\overline{B_{2}} \subset V \backslash B_{1}$, the space $\mathfrak{X}_{T}\left(\mathbb{C} \backslash B_{2}\right)$ is closed and $\left|\lambda_{j}-\lambda_{k}\right| \neq r_{2} \quad(j>k)$. If we continue in this way, we obtain the required sequence of open $\operatorname{discs} \mathcal{U}_{E}=\left(B_{j}\right)_{j}$ covering $E$.

For each $z_{0} \in V \backslash E$ we next find a simply connected open set $W_{z_{0}}$ such that $z_{0} \in W_{z_{0}} \subset V \backslash E$ and $W_{z_{0}} \backslash B_{n} \neq \emptyset$ for each $B_{n} \in \mathcal{U}_{E}$. If $z_{0} \notin \bigcup_{n} B_{n}$, choose $r>0$ such that $B\left(z_{0}, r\right) \subset V \backslash E$ and set $W_{z_{0}}=B\left(z_{0}, r\right)$. Suppose then that $z_{0} \in \bigcup_{n} B_{n} \backslash E$. Since the sets $B_{n}$ are mutually disjoint, there is only one $j$ with $z_{0} \in B_{j}$, and since the set
$E$ is countable, there is a $\theta, 0 \leq \theta<2 \pi$ such that $\left\{z_{0}+t e^{i \theta}: t \geq 0\right\} \cap E=\emptyset$. Let $t_{0}=$ $\min \left\{t \geq 0: z_{0}+t e^{i \theta} \notin B_{j}\right\}$. Since the set $S:=\left\{z_{0}+t e^{i \theta}: 0 \leq t \leq t_{0}\right\}$ is compact and the set $E \cup \partial V$ is closed, there is an $\varepsilon>0$ such that the set $W_{z_{0}}:=\{z \in \mathbb{C}: \operatorname{dist}\{z, S\}<\varepsilon\}$ is disjoint with $E \cup \partial V$. Clearly $W_{z_{0}}$ is an open simply connected set such that $z_{0} \in W_{z_{0}} \subset$ $V \backslash E \subset \rho_{K}(T)$. If $G$ is the component of $\rho_{K}(T)$ containing $W_{z_{0}}$, then $\mathfrak{X}_{T}\left(\mathbb{C} \backslash W_{z_{0}}\right)=$ $R^{\infty}(T-\lambda)$ for every $\lambda \in G$. In particular, $\mathfrak{X}_{T}\left(\mathbb{C} \backslash W_{z_{0}}\right)$ is closed and $W_{z_{0}} \cap W_{z_{1}}=\emptyset$ if $z_{0}, z_{1} \in V \backslash E$ are such that $\mathfrak{X}_{T}\left(\mathbb{C} \backslash W_{z_{0}}\right) \neq \mathfrak{X}_{T}\left(\mathbb{C} \backslash W_{z_{1}}\right)$. By construction, $W_{z} \backslash B_{k} \neq$ $\emptyset$ and $B_{k} \backslash W_{z} \neq \emptyset$ whenever $z \in V \backslash E$ and $B_{k} \in \mathcal{U}_{E}$. Thus, if $\mathcal{U}_{K}=\left\{W_{z}: z \in V \backslash E\right\}$ and $\mathcal{U}=\mathcal{U}_{K} \cup \mathcal{U}_{E}$, then $\mathcal{U}$ is an open cover of $V$ satisfying the hypotheses of Lemma 1 .

As in Lemma 1, let $M=\bigcap_{D \in \mathcal{U}} \mathfrak{X}_{T}(\mathbb{C} \backslash D)$ and let $\widetilde{T}: X / M \rightarrow X / M$ be the operator induced by $T$. By Lemma 1 (iii), we have $(T-z) M=M$ for all $z \in V$. We show that $\widetilde{T}-z$ is bounded below for each $z \in V \backslash E$, i.e., if $z \in V \backslash E$ and $\left(x_{n}\right)_{n} \subset X$ is such that $(\widetilde{T}-z) \tilde{x}_{n} \rightarrow 0$ in $X / M$, then $\tilde{x}_{n} \rightarrow 0$ in $X / M$.

Fix $z \in V \backslash E$ and let $x \in \operatorname{ker}(T-z)$. Then $\operatorname{ker}(T-z) \subset R^{\infty}(T-z)=\mathfrak{X}_{T}(\mathbb{C} \backslash$ $W_{z}$ ), and so there exists $g \in H\left(W_{z}, X\right)$ so that $(T-\omega) g(\omega)=x$ for all $\omega \in W_{z}$. If $h=(T-z) g$, then $h \in \operatorname{ker} T_{W_{z}}$ and, since $W_{z} \in \mathcal{U}$, it follows from Lemma 1 (ii) that $h: W_{z} \rightarrow M$. In particular, $x=h(z) \in M$. Thus $\operatorname{ker}(T-z) \subset M$.

A sequence $\left(x_{n}\right)_{n} \subset X$ satisfies $(\widetilde{T}-z) \tilde{x}_{n} \rightarrow 0$ only if there exists $\left(y_{n}\right)_{n} \subset M$ so that $(T-z) x_{n}-y_{n} \rightarrow 0$ in $X$. Since $(T-z) M=M$, there exists $\left(w_{n}\right)_{n} \subset M$ so that $(T-$ z) $w_{n}=y_{n}$ and therefore, $(T-z)\left(x_{n}-w_{n}\right) \rightarrow 0$. Since $\operatorname{ran}(T-z)$ is closed, it follows that dist $\left(x_{n}-w_{n}, \operatorname{ker}(T-z)\right) \rightarrow 0$. $\operatorname{But} \operatorname{ker}(T-z) \subset M$, and so $\operatorname{dist}\left(x_{n}, M\right) \rightarrow 0$, i.e., $\tilde{x}_{n} \rightarrow 0$ in $X / M$ as required. Hence $\widetilde{T}-z$ is bounded below for each $z \in V \backslash E$. In particular, $V \backslash E \subset \rho_{K}(\widetilde{T})$.

We wish to show that $\widetilde{T}_{V}$ is injective with closed range. Suppose then that $\left(f_{n}\right)_{n}$ is a sequence in $H(V, X / M)$ such that $\widetilde{T}_{V} f_{n} \rightarrow 0$. In order to show that $f_{n} \rightarrow 0$ in $H(V, X / M)$, it suffices to show that $p_{F}\left(f_{n}\right)=\sup _{z \in F}\left\|f_{n}(z)\right\| \rightarrow 0$ for every closed rectangle $F \subset V$. Suppose that $a, b, c, d$ are real numbers such that the rectangle $F=[a, b] \times[c, d] \subset V$. Choose $\delta>0$ so that $[a-\delta, b+\delta] \times[c-\delta, d+\delta] \subset V$. Since $E$ is countable, the projections $P_{1}=\{\operatorname{Re} \lambda: \lambda \in E\}$ and $P_{2}=\{\operatorname{Im} \lambda: \lambda \in E\}$ are countable and we may choose $a^{\prime}, b^{\prime} \in \mathbb{R} \backslash P_{1}$ and $c^{\prime}, d^{\prime} \in \mathbb{R} \backslash P_{2}$ so that $a-\delta<$ $a^{\prime}<a<b<b^{\prime}<b+\delta$ and $c-\delta<c^{\prime}<c<d<d^{\prime}<d+\delta$. Define $\Gamma$ to be the positively oriented boundary of the rectangle $\left[a^{\prime}, b^{\prime}\right] \times\left[c^{\prime}, d^{\prime}\right] \subset V$. Then $\Gamma \subset V \backslash E$ surrounds $F$ in the sense of Cauchy's theorem. By continuity of the minimum modulus function $z \mapsto \gamma(\widetilde{T}-z)$ on $V \backslash E$, there is a constant $c>0$ so that $\sup _{z \in \Gamma}\left\|f_{n}(z)\right\| \leq$ $c \sup _{z \in \Gamma}\left\|(\widetilde{T}-z) f_{n}(z)\right\|$ for all $n$. Thus for each $\lambda \in F$ the maximum principle implies that

$$
\left\|f_{n}(\lambda)\right\| \leq \sup _{z \in \Gamma}\left\|f_{n}(z)\right\| \leq C p_{\Gamma}\left(\widetilde{T}_{V} f_{n}\right)
$$

where $C=c|\Gamma| /(2 \pi \operatorname{dist}(\Gamma, F))$. Thus $p_{F}\left(f_{n}\right) \rightarrow 0$ as $n \rightarrow \infty$ as required. Since $(T-$ $z) M=M$ for all $z \in V$ by part (iii) of Lemma 1, Leiterer's theorem implies that $T_{V} H(V, M)=H(V, M)$, and $T_{V}$ therefore has closed range in $H(V, X)$ by [9, Prop. 2.1]; the theorem is established.

For $T \in B(X)$ denote by $K(T)$ the analytic core of $T$, i.e., the set of all $x_{0} \in X$ such that there exists a sequence $\left(x_{n}\right)_{n} \subset X$ such that $T x_{n}=x_{n-1} \quad(n \geq 1)$ and sup $\left\|x_{n}\right\|^{1 / n}<$ $\infty$. Clearly $K(T)=\bigcup_{n} \mathfrak{X}_{T}(\mathbb{C} \backslash D(0,1 / n))$. This set has been shown to play a significant role in the Fredholm theory of Banach space operators; see, for example [1].

Corollary 6. Let $T \in B(X)$ and let $V \subset \mathbb{C}$ be an open set. Suppose that $K(T-z)$ is closed for each $z \in V$ and that the set $\{z \in V: \operatorname{ran}(T-z)$ is not closed $\}$ is countable. Then $T$ has (CR) on $V$.

Proof. Let $z \in V$ and $K(T-z)$ be closed. Clearly $(T-z) K(T-z)=K(T-z)$ and, by the Banach open mapping theorem, there is an $\varepsilon>0$ such that $K(T-z)=$ $\mathfrak{X}_{T}(\mathbb{C} \backslash B(z, \varepsilon))$. In fact, $\varepsilon=\gamma\left(\left.(T-z)\right|_{K(T-z)}\right)^{-1}$. Clearly $\mathfrak{X}_{T}(\mathbb{C} \backslash W)=K(T-z)$ for each open set $W$ with $z \in W \subset B(z, \varepsilon)$. By Theorem 5, $T$ has (CR) on $V$.

A generalized Kato decomposition for $T \in B(X)$ is a pair of subspaces $X_{1}, X_{2} \in$ $\operatorname{Lat}(T)$ such that $X=X_{1} \oplus X_{2},\left.T\right|_{X_{1}}$ is Kato and $\left.T\right|_{X_{2}}$ is quasinilpotent. The operator $T$ is said to be of Kato-type if $\left.T\right|_{X_{2}}$ is nilpotent. It is well known that semi-Fredholm operators are of Kato-type, see e.g. [1], [10].

If $\rho_{g k}(T)$ denotes the set of $\lambda \in \mathbb{C}$ such that $T-\lambda$ has a generalized Kato decomposition, then $\rho_{g k}(T)$ is open and $\rho_{g k}(T) \cap \sigma_{K}(T)$ accumulates only on $\partial \rho_{g k}(T)$. Indeed, suppose that $0 \in \rho_{g k}(T)$ and that $X_{1}, X_{2} \in \operatorname{Lat}(T)$ such that $X=X_{1} \oplus X_{2}$, $\left.T\right|_{X_{1}}$ is Kato and $\left.T\right|_{X_{2}}$ is quasinilpotent. If $\varepsilon>0$ is such that $B(0, \varepsilon) \subset \rho_{K}\left(\left.T\right|_{X_{1}}\right)$, then for $0<|z|<\varepsilon,(T-z) X_{2}=X_{2}$. Thus $\operatorname{ran}(T-z)=(T-z) X_{1} \oplus X_{2}$ is closed and $N^{\infty}(T-z)=N^{\infty}\left(\left.T\right|_{X_{1}}-z\right) \subset R^{\infty}\left(\left.T\right|_{X_{1}}-z\right)$.

Moreover, if $T$ has generalized Kato decomposition ( $X_{1}, X_{2}$ ) as above, then by the remarks preceding Lemma $1, R^{\infty}\left(\left.T\right|_{X_{1}}\right) \subseteq K(T)$. On the other hand, if $x \in K(T)$, write $x=u_{0}+v_{0}$ with $u_{0} \in X_{1}$ and $v_{0} \in X_{2}$. We show that $v_{0}=0$.

Suppose to the contrary that $v_{0} \neq 0$. Then, by definition, there are sequences $\left(u_{n}\right) \subset X_{1}$ and $\left(v_{n}\right) \subset X_{2}$ such that $T u_{n}=u_{n-1}$ and $T v_{n}=v_{n-1}$ for all $n$ and $C:=$ sup $\left\|u_{n}+v_{n}\right\|^{1 / n}<\infty$. Let $P \in B(X)$ be the projection with ker $P=X_{1}$ and ran $P=X_{2}$. We have $\left\|v_{n}\right\|^{1 / n}=\left\|P\left(u_{n}+v_{n}\right)\right\|^{1 / n} \leq\|P\|^{1 / n} \cdot C$. Thus
a contradiction to the assumption that $\left.T\right|_{X_{2}}$ is quasinilpotent. Hence $v_{0}=0$ and $K(T) \subseteq X_{1}$. Therefore

$$
K(T)=K\left(\left.T\right|_{X_{1}}\right)=R^{\infty}\left(\left.T\right|_{X_{1}}\right)
$$

in particular, $K(T)$ is closed.
Thus we have established the following special case of Corollary 6 , generalizing [ 9 , Theorem 2.5].

Corollary 7. $T \in B(X)$ has $(C R)$ on $\rho_{g k}(T)$.

Duality and weak-* closed ranges. Let $\mathbb{C}_{\infty}=\mathbb{C} \cup\{\infty\}$ be the Riemann sphere and for $U$ an open neighborhood of $\infty$, let $P(U, X)$ denote the Fréchet space of analytic functions $f: U \rightarrow X$ with $f(\infty)=0$. If $T \in B(X)$, then $T$ induces a continuous mapping $T^{U}$ on $P(U, X)$ defined by $T^{U} f(z)=(T-z) f(z)+\lim _{|\omega| \rightarrow \infty} \omega f(\omega)$. For $F$ closed in $\mathbb{C}_{\infty}$ with $\infty \in F$, let $P(F, X)$ denote the inductive limit of the spaces $P(U, X)$, $U \supset F$ open; i.e., $P(F, X)$ is the $(L F)$-space consisting of germs of analytic $X$-valued functions defined in a neighborhood of $F$ and vanishing at infinity. If $\infty \in F$ is closed and $U$ is open with $F \subset U$, let $i_{U}: P(U, X) \rightarrow P(F, X)$ be defined by $i_{U} f=[f]$. Then a mapping $S$ from $P(F, X)$ to an arbitrary topological vector space $E$ is continuous if
and only if $S \circ i_{U}$ is continuous for every open neighborhood $U$ of $F$. In particular, the mappings $T^{U}$ induce a continuous mapping $T^{F}$ on $P(F, X)$. Recall further the Grothendieck-Köthe duality principle: given $V \subset \mathbb{C}$ open, the Fréchet space $H\left(V, X^{*}\right)$ may be canonically identified with the strong dual of $P\left(\mathbb{C}_{\infty} \backslash V, X\right)$ via

$$
\langle f, g\rangle=\int_{\gamma}\langle f(z), \widetilde{g}(z)\rangle d z,
$$

where $f \in H\left(V, X^{*}\right), \widetilde{g} \in P(U, X)$ is a representative of $g \in P\left(\mathbb{C}_{\infty} \backslash V, X\right)$ and $\gamma$ is a contour surrounding $\mathbb{C} \backslash U$ in $V$. In this sense, we have that $T_{V}^{*}=\left(T^{\complement \backslash V}\right)^{*},[6$, Theorem 2.5.12 and Lemma 2.5.13]. Moreover, by the duality results of Albrecht and Eschmeier, specifically, Theorem 21 and the proof of Theorem 5 of [2], $T^{*}$ has property $(\beta)$ on $U$ if and only if $T^{F} P(F, X)=P(F, X)$ for every closed set $F \subseteq \mathbb{C}_{\infty}$ with $\mathbb{C}_{\infty} \backslash U \subseteq F$. In this case, for every open $V \subseteq U, T_{V}^{*}$ is injective with weak $-*$ closed range in $H\left(V, X^{*}\right)$ by a theorem of Köthe, [ 6 , Theorem 2.5.9].

Let us say that $T^{*}$ has the property $(\mathrm{CR})^{\text {weak-* }}$ on $U$ provided that ran $T_{V}^{*}$ is weak-* closed in $H\left(V, X^{*}\right)$ for every open $V \subseteq U$.

Proposition 8. Let $T \in B(X)$ and $U \subset \mathbb{C}$ open and suppose that $F$ is closed in $\mathbb{C}$ with $\mathbb{C} \backslash U \subset F$.
(i) If $T$ has $(C R)$ on $U$, then $\mathfrak{X}_{T}(F)={ }^{\perp} \mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash F)$, the preannihilator of $\mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash$ $F):=\bigcup\left\{\mathfrak{X}_{T^{*}}^{*}(K): K\right.$ compact, $\left.K \subset \mathbb{C} \backslash F\right\}$.
(ii) If $T^{*}$ has $(C R)^{\text {weak-* }}$ on $U$, then $\mathfrak{X}_{T^{*}}^{*}(F)=\mathfrak{X}_{T}(\mathbb{C} \backslash F)^{\perp}$, the annihilator of $\mathfrak{X}_{T}(\mathbb{C} \backslash$ $F):=\bigcup\left\{\mathfrak{X}_{T}(K): K\right.$ compact, $\left.K \subset \mathbb{C} \backslash F\right\}$. In particular, $\mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash V)$ is weak-* closed whenever $V \subseteq U$ is open.

Proof. If $F$ is closed and $\mathbb{C} \backslash U \subseteq F$, then $V:=\mathbb{C} \backslash F$ is an open subset of $U$. Thus $\operatorname{ran} T_{V}$ is closed in case (i), and $\operatorname{ran} T_{V}^{*}$ is weak-* closed in case (ii). The result now follows from parts (c) and (d) of [4, Lemma I.2.5]; alternatively, one could argue as in the proof of [6, Prop 2.5.14].

As a consequence of the Proposition 8, we obtain weak-* analogs of Theorems 4 and 5.

THEOREM 9. There is a largest open set $V$ on which $T^{*} \in B\left(X^{*}\right)$ has $(C R)^{\text {weak-*. }}$.
Proof. First we establish an analog of Lemma 3. Suppose that $T^{*} \in B\left(X^{*}\right)$ has $(\mathrm{CR})^{\text {weak }-*}$ on open sets $V_{1}$ and $V_{2}$ and that $\Omega$ is an open subset of $V_{1} \cup V_{2}$. Let $\Omega_{1} \subset V_{1} \cap \Omega, \Omega_{2} \subset V_{2} \cap \Omega$ be open sets and $\mathcal{U}$ an open cover of $\Omega$ as in Lemma 2. Let $M=\bigcap_{D \in \mathcal{U}} \mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash D)$. By Proposition 8, for each $D \in \mathcal{U}, \mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash D)$ is weak-* closed and therefore $M$ is also weak-* closed. Evidently, the restriction mapping $\left.f \mapsto f\right|_{\Omega_{j}}$ from $H\left(\Omega, X^{*}\right)$ to $H\left(\Omega_{j}, X^{*}\right)$ is weak-* continuous and intertwines $T_{\Omega}^{*}$ and $T_{\Omega_{j}}^{*}, j=1,2$. Therefore, if $f \in \overline{\operatorname{ran} T_{\Omega}^{*}}{ }^{\text {weak }}$, then $\left.f\right|_{\Omega_{j}} \in \overline{\operatorname{ran} T_{\Omega_{j}}^{*}}{ }^{\text {weak-* }}$, and so, by assumption, there are $g_{j} \in H\left(\Omega_{j}, X^{*}\right)$ such that $\left.f\right|_{\Omega_{j}}=T_{\Omega_{j}}^{*} g_{j}$ for each $j$. As in the proof of Lemma 3, it follows from Lemma 2 that $T_{\Omega_{1} \cap \Omega_{2}}^{*}\left(g_{1}-g_{2}\right)=0$, and so $\left(g_{1}-g_{2}\right)\left(\Omega_{1} \cap \Omega_{2}\right) \subset M$ by Lemma 1 (ii). Thus $\left.\widetilde{g}_{1}\right|_{\Omega_{1} \cap \Omega_{2}}=\left.\widetilde{g}_{2}\right|_{\Omega_{1} \cap \Omega_{2}}$ in $H\left(\Omega_{1} \cap \Omega_{2}, X^{*} / M\right)$, and we can define $h \in H\left(\Omega, X^{*} / M\right)$ by $h(z)=\widetilde{g}_{j}(z)$ for $z \in \Omega_{j}$. We have $\tilde{f}=\left(T^{*} \widetilde{\Gamma}_{\Omega} h\right.$ and, by Gleason's theorem, there exists $g \in H\left(\Omega, X^{*}\right)$ such that $h=\widetilde{g}$. Moreover, $f-T_{\Omega}^{*} g \in H(\Omega, M)$, and so again Lemma 1 (iii) and Leiterer's theorem imply that $f-T_{\Omega}^{*} g=T_{\Omega}^{*} k$ for some $k \in H(\Omega, M)$. Hence $f=T_{\Omega}^{*}(g+k) \in \operatorname{ran} T_{\Omega}^{*}$. Thus $T^{*} \in B\left(X^{*}\right)$ has $(\mathrm{CR})^{\text {weak }-*}$ on $V_{1} \cup V_{2}$.

To complete the argument, we adapt the proof of Theorem 4 similarly. The routine details are left to the reader.

Recall that $\operatorname{ran} T^{*}$ is weak $-*$ closed in $X^{*}$ if and only if $\operatorname{ran} T$ is closed in $X,[6$, A.1.10]. Also, $\sigma_{K}\left(T^{*}\right)=\sigma_{K}(T),[\mathbf{1 0}$, II. 12 Theorem 11].

Theorem 10. Let $T \in B(X)$ and let $V \subset \mathbb{C}$ be an open set. Suppose that the set $\{z \in V: \operatorname{ran}(T-z)$ is not closed $\}$ is countable and that, for all $z \in V$, there is a $r_{0}>0$ for which $\mathfrak{X}_{T}(\mathbb{C} \backslash B(z, r))$ is weak $-*$ closed for all $r \in\left(0, r_{0}\right)$. Then $T^{*}$ has $(C R)^{\text {weak-* }}$ on $V$.

Proof. Since the conditions of the theorem are inherited by every open subset $U$ of $V$, it suffices to show that $T_{V}^{*}$ has weak-* closed range. Let $E:=V \cap \sigma_{K}(T)$ and construct a covering $\mathcal{U}=\mathcal{U}_{K} \cup \mathcal{U}_{E}$ exactly as in the proof of Theorem 5, noting that if $z_{0} \in V \backslash E$ and if $\lambda$ is in the component of $\rho_{K}(T)$ containing $z_{0}$, then $\mathfrak{X}_{T^{*}}^{*}\left(\mathbb{C} \backslash W_{z_{0}}\right)=$ $R^{\infty}\left(T^{*}-\lambda\right)$ is weak-* closed. Let $M=\bigcap_{D \in \mathcal{U}} \mathfrak{X}_{T^{*}}^{*}(\mathbb{C} \backslash D)$ and denote by $\left(T^{*}\right)$ the operator on $X^{*} / M$ induced by $T^{*}$. Then Lemma 1 (iii) implies that $\left(T^{*}-z\right) M=M$ for all $z \in V$, and, as in the proof of Theorem $5,\left(T^{*}\right)-z$ is bounded below for each $z \in V \backslash E$. The conclusion now follows from [9, Prop. 3.1], noting that, as indicated in the proof of Theorem 5, it suffices in [9, Prop. 3.1] that the exceptional set $E$ be merely countable rather than discrete.

Corollary 11. Let $T \in B(X)$ and let $V \subset \mathbb{C}$ be an open set. Suppose that the analytic core $K\left(T^{*}-z\right)$ is weak-* closed for each $z \in V$ and that the set $\{z \in V$ : $\operatorname{ran}(T-z)$ is not closed $\}$ is countable. Then $T^{*}$ has $(C R)^{\text {weak-* }}$ on $V$. In particular, $T^{*}$ has $(C R)^{\text {weak }-*}$ on $\rho_{g k}(T)$.

Proof. The first statement follows from Theorem 10 just as Corollary 6 follows from Theorem 5. If $T \in B(X)$ has generalized Kato decomposition ( $X_{1}, X_{2}$ ), then ( $X_{2}^{\perp}, X_{1}^{\perp}$ ) is a generalized Kato decomposition for $T^{*}$ consisting of weak-* closed subspaces of $X^{*}$. Thus $\rho_{g k}(T) \subseteq \rho_{g k}\left(T^{*}\right)$. If $z \in \rho_{g k}(T)$, and ( $X_{1}, X_{2}$ ) is a generalized Kato decomposition for $T$, then $K\left(T^{*}-z\right)=K\left(\left.\left(T^{*}-z\right)\right|_{X_{2}^{\perp}}\right)=R^{\infty}\left(\left.\left(T^{*}-z\right)\right|_{X_{2}^{\perp}}\right)$; in particular, $K\left(T^{*}-z\right)$ is weak $-*$ closed in $X^{*}$. Since $\rho_{g k}(T) \cap \sigma_{K}(T)$, is discrete, the last result now follows.

We are indebted to the referee and editor for their careful reading that substantially contributed to this paper.
