CONSTRUCTION PRINCIPLE AND TRANSFINITE INDUCTION UP TO $\varepsilon_0$

MARIKO YASUGI

(Received 16 July 1980)

Communicated by J. N. Crossley

Abstract

What we call here the "construction principle" is a principle on the ground of which some functionals can be defined; the domain and the range of such a functional consist of some "computable" functionals of various finite types. The principle above is considered here as the basis of the functional interpretation of transfinite induction up to $\varepsilon_0$. It is concretely represented as the "term-forms", where every term-form is shown to be "computable" in some sense.

It is well-known that the accessibility of the ordered structure which is a canonical representation of the ordinals below $\varepsilon_0$ (the first $\varepsilon$-number) cannot be proved in elementary number theory (see Gentzen (1943)), while it is provable if an analytic method is employed, namely, it is provable in first order arithmetic augmented by the $\Pi_1^1$-induction (see Gentzen (1943)). The full power of the $\Pi_1^1$-induction is not necessary, however, and attempts have been made to establish the accessibility along more concrete lines, for example in Gentzen (1936) and Takeuti (1975).

In this article we are to propose a theory of "construction principle", a principle on the ground of which some functionals can be defined; the domain and the range of such a functional consist of some "computable" functionals of various finite types. The principle above is considered here as the basis of the functional interpretation of transfinite induction up to $\varepsilon_0$.

The article begins with a glossary of the terminology and symbolism (Section I). Section 2 consists in the interpretation of transfinite induction up to $\varepsilon_0$ in an arithmetic with infinite reasoning. Although the local technicalities used in this
section are borrowed from Section 2 of Gentzen (1943), our scheme is a "uniform version" of the provability demonstration, so to speak, thus reaching up to $\varepsilon_0$. The reason why we devote one section to this endeavor is to facilitate our ultimate objective, namely, the functional interpretation of transfinite induction up to $\varepsilon_0$, an informal account of which is given in Section 3.

Our construction principle, the principle behind the functional interpretation of Section 3, is formulated and developed in Section 4. It is concretely represented as the "term-forms", where every term-form is shown to be "computable" in some sense. Section 5 concludes the functional interpretation; the functional construction given in Section 3 can be interpreted in the theory of the term-forms.

We have developed the theory of "construction principle" just to interpret $\varepsilon_0$. Mathematical relationships of this theory to other theories as well as further developments and applications in this line are left open as a problem to be worked on in the future.

Some theories of generalization over Gödel's computable functionals have appeared, a few of which are listed as references; they were developed for their respective purposes.

The idea of "construction principle" was first presented at the workshop on proof-theory which was taken place in May, 1979, at the Research Institute for Mathematical Sciences in Kyoto. The author is grateful to the participants for their valuable comments and discussions.

1. Preliminary definitions

**Definition 1.1.** The canonical well-ordering system $(E, \prec)$ whose order-type is known to be $\varepsilon_0$ is defined as usual; $0$ is the basic element and $\omega^a$ and $a_1 + \cdots + a_m$ are compound elements, where $a_1, \ldots, a_m$ are monomials. $\omega^a$ will also be written as $\exp(\omega, a)$. The equality relation $=$ and the order $\prec$ are defined as usual for the elements of $E$, and we assume that the components (monomials) of an element of $E$ are arranged in the non-increasing order.

The linearity of the order $\prec$ is easily established, hence will be assumed throughout.

$\omega_n$ abbreviates the following:

$$\omega_1 = \omega^0 = 1, \quad \omega_2 = \omega^1 = \omega \quad \text{and} \quad \omega_{n+1} = \exp(\omega, \omega_n).$$

**Definition 1.2.** An $E$-element $a$ is said to be accessible (with regards to $\prec$) if, given any $\prec$-decreasing sequence from $E$ led by $a$, there is a method (uniform
for all such sequences) to show that it is finite. \(\prec\) (or \((E, \prec)\)) is said to be accessible if there is a uniform method to establish that every \(E\)-element is accessible.

\textit{Note.} We do not specify the nature of the "method" here.

**Definition 1.3.** \(ht(a)\), the height of an \(E\)-element \(a\), which is a natural number, is defined as follows.

\[
ht(0) = ht(\omega_0) = 0, \quad ht(1) = ht(\omega_1) = 1, \quad ht(\omega^n) = ht(a) + 1,
\]

\[
ht(a_1 + \cdots + a_m) = \max(ht(a_1), \ldots, ht(a_m))
\]

(= \(ht(a_1)\); according to our assumption on the order of \(a_1, \ldots, a_m\)).

Let \(f\) be a sequence from \(E\). \(ht(f)\) is defined to be \(ht(f(0))\).

In passing, the definition implies that for a decreasing sequence \(f\)
\[
ht(f(i)) \leq ht(f), \quad \text{for } i = 0, 1, 2, \ldots
\]

**Definition 1.4.** An \(E\)-element consisting of equal monomials alone will be said to be homogeneous. \(\omega^a + \cdots + \omega^a\) with \(l\) components will be abbreviated as \(\omega^a\). If \(a = \exp(\omega, a_1)l_1 + \cdots + \exp(\omega, a_m)l_m, a_1, \ldots, a_m\) all distinct, then each \(\exp(\omega, a_i)l_i\) is called a homogeneous term of \(a, a_1\) the highest power of \(a\) and \(\exp(\omega, a_i)l_i\) the homogeneous term of the highest power (of \(a\)).

\(p(\omega^a) = b; \ h_p(a) = \text{the highest power of } a; \ h_p(t(a)) = \text{the homogeneous term of the highest power of } a.\)

2. An accessibility proof in an infinite system

Here we formulate an accessibility proof of \((E, \prec)\) in a semiformal system with a restricted \(\omega\)-rule. We take over Gentzen’s demonstration of the accessibility proof for \(\omega\), for each \(n\) (see Section 2 of Gentzen (1943)) in local technicalities. The difference lies in that in his case the demonstration consists of a finite (hence concrete) repetition of the derivations of a same sort, while here such a repetition be regarded as a principle, rather than a practice; this difference is what leads us to the accessibility proof for \((E, \prec)\).

**Definition 2.1.** \(\Pi\) will denote a formulation of arithmetic with function quantifications and the primitive recursive infinite rule, where the mathematical induction and the usual \(\forall\)-introduction is also admitted if the derivation up to it is finite. No sophisticated rules such as the choice rule are involved.
We assume the arithmetization of \((E, <)\) in \(\Pi\). We shall use the following notational convention.

\(a, b, c, \ldots, x, y, z, \ldots, r, \ldots\) range over the elements of \(E\); \(m, n, \ldots, i, j, \ldots\) will range over natural numbers. \(\forall x (E(x) \supset A)\) \((E(x)\) represents \(x \in E\)) will often be abbreviated to \(\forall x A\).

**DEFINITION 2.2.** A formula in \(\Pi\), \(A_i(a)\), will be defined for each \(i\), \(i = 0, 1, 2, \ldots\)

- \(A_0(a): \forall f\) (If \(f\) is a decreasing sequence from \(E\) led by \(a\), then \(f\) is finite.)

Suppose \(A_i(a)\) has been defined. Let \(A_i^*(a)\) abbreviate \(\forall y (y \leq a \supset A_i(y))\). Then,

\[A_{i+1}(a): \forall x (A_i^*(x) \supset A_i^*(x + \omega^a))\]

For the notational convenience, we shall write \(A(i; a)\) for \(A_i(a)\). The reader should be aware that \(A(i; a)\) is not a single formula with a variable \(i\), but a distinct formula for each \(i\).

**THEOREM 1.** \(\forall n A(0; \omega_n)\) is provable in \(\Pi\).

The theorem implies the

**CONCLUSION.** \(\forall x (E(x) \supset A(0; x))\) is provable in \(\Pi\). In other words, the accessibility of \((E, <)\) is established in \(\Pi\).

*Note.* The "uniform" method in Definition 1.2 is here the reasoning admissible in \(\Pi\).

**DEFINITION 2.3.** \(\forall n (\{a\} B(a))\) stands for

\(\forall a (\forall x (x < a \supset B(x)) \supset B(a))\)

for any formula \(B\).

**PROPOSITION 2.1.** The following 1 through 6 are provable in \(\Pi\) for each \(k\) without applications of the infinite rule; furthermore the proofs are primitive recursive in \(k\).

1. \(A(0; 0)\),
2. \(A(k + 1; 0) \rightarrow A(k + 1; \omega_0)\),
3. \(Pr(\{x\} A(0; x))\),
4. \(Pr(\{x\} A(k; x)) \rightarrow Pr(\{x\} A(k + 1; x))\),
5. \(Pr(\{x\} A(k; x)) \rightarrow A(k + 1; 0)\),
6. From \(Pr(\{x\} A(k; x))\) and \(A(k + 1; 0) \rightarrow A(k + 1; a)\) we can deduce \(A(k; 0) \rightarrow A(k; \omega^a)\).
PROOF OF THEOREM 1 from Proposition 2.1. For each \( k \),

7. **Proof (**) \( \Pr(\{x\} A(k; x)) \)

by 3 and repeated applications of 4. For any fixed \( n \), let \( k \) range over \( n, n - 1, \ldots, 1, 0 \) consecutively in 5 and 6, where \( a = \omega_{n-k} \) in 6. 2 with \( k = n \)

and consecutive applications of 5, 7 and 6 for \( k = n, n - 1, \ldots, 1, 0 \) yield in succession:

\[
A(n + 1; 0) \rightarrow A(n + 1; \omega_0),
A(n; 0) \rightarrow A(n; \omega_1),
\vdots
A(1; 0) \rightarrow A(1; \omega_n),
A(0; 0) \rightarrow A(0; \omega_{n+1}).
\]

This last sequent and 1 above yield \( A(0; \omega_n) \) in \( \Pi \) for every \( n \); the derivations are primitive recursive in \( n \). The infinite rule now yields \( \forall n A(0; \omega_n) \) in \( \Pi \).

**Proof of the Conclusion.** For any \( a \) in \( E \), the least \( n \) such that \( a \leq \omega_n \) can be determined primitive recursively from \( a \), say \( g(a) \). So, for each \( a \), \( A(0; \omega_{g(a)}) \) is provable in \( \Pi \) without infinite rule; furthermore the derivation is primitive recursive in \( a \). (This fact can be established by modifying the last part of the proof of Theorem 1.) \( A(0; \omega_{g(a)}) \) implies \( A(0; a) \). Now apply the infinite rule to obtain \( \forall x (E(x) \supset A(0; x)) \).

Notice that the theorem (as well as the conclusion) has been established by a single application of the infinite rule.

**Proof of Proposition 2.1.** Since the proofs are essentially the same as those of Gentzen (1943), we shall briefly remark on one point.

4 of Proposition 2.1. According to Gentzen, we let \( d \) be \( fu_1(b, c, a) \) and let \( n \) be \( fu_2(b, c, a) \). By the definition of \( A \), we have

1. \( A(k + 1; d), A^*(k; c + \omega^d m) \rightarrow A^*(k; c + \omega^d(m + 1)) \),

2. \( A(k + 1; d), A^*(k; c) \rightarrow A^*(k; c + \omega^d n) \).

Notice that (1) and (2) can be established uniformly in (independently of) \( k \). Deducing the required conclusion from (2) is a straightforward process.

**3. Functional interpretation**

A careful analysis of the proof procedure in Section 2 leads us to a certain construction principle, based on which the accessibility of \( (E, <) \) can be
established. We first present an informal account of construction in order to get
the general idea, the formulation of which will be given in the next two sections.

**Definition 3.1.** Finite types are defined as usual (see Gödel (1958), Hindley,
Lercher and Seldin (1972), Yasugi (1963)): 0 is the ground type (representing
natural numbers); \( s \rightarrow t \) is a type if \( s \) and \( t \) are, representing functionals which
map the objects of type \( s \) to those of type \( t \). \( s_1 \rightarrow (s_2 \rightarrow (\cdots (s_n \rightarrow t) \cdots )) \) will
be abbreviated to \( s_1, s_2, \ldots, s_n \rightarrow t \).

A type function is a primitive recursive function whose values are finite types.
We list some useful type functions below.

\[
\begin{align*}
[0] &= 1 \rightarrow 1, \quad \text{where } 1 = 0 \rightarrow 0. \\
[i + 1] &= 0 \rightarrow ([i] \rightarrow [i]), \quad \text{or } 0, [i] \rightarrow [i]. \\
(i) &= 0 \rightarrow ([i] \rightarrow [i]), \quad \text{or } 0, [i] \rightarrow [i]. \\
\langle i \rangle &= \{i\} \rightarrow \{i + 1\}. \\
\|i\| &= \{i\}, \quad ([i + 1] \rightarrow [i + 1]), \quad [i] \rightarrow [i].
\end{align*}
\]

\( \phi, \psi, \chi, \ldots \) will be used for functional variables; a functional variable of type
\( t \) will be denoted by \( \phi', \psi', \text{etc.} \), but we omit the type symbol whenever possible.

**Definition 3.2.** \( G_0(\phi^{[i]}, a) \) will be defined for each \( i, i = 0, 1, 2, \ldots \).

\( G_0(\phi^{[0]}, a) \): Given a function \( f \), if \( f \) is a decreasing sequence from \( \mathbb{E} \) led by an
\( x \ll a \), then \( \phi^{[0]}(f) \) is a decreasing sequence from \( \mathbb{E} \) satisfying that \( \phi^{[0]}(f)(j) \) is
the homogeneous term of the highest power of \( f(n_j) \) for some \( n_j \), where \( \{n_j\} \) is
an increasing sequence and \( n_0 = 0 \), and such that if \( \phi^{[0]}(f) \) is finite, then so is \( f \).
(See Section 1 for homogeneous terms, etc.)

This is the way I would like to describe \( G_0 \). Dissatisfaction has been expressed
to me, however, as to the informal manner as it stands, hence an attempt of a
formulation of \( G_0 \) in a semi-formalism.

Let \( f \) stand for a function from natural numbers to \( \mathbb{E} \). We call such a function
a sequence from \( \mathbb{E} \). We include finite sequences here. \( f \) is said to be decreasing if
\( f(n) < f(m) \) when \( n > m \). \( f \) is said to be led by \( x \) an element of \( \mathbb{E} \) if \( f(0) = x \).
Now \( G_0(\phi^{[0]}, a) \) can be expressed as follows.
\[ \forall f \lbrakk \text{\{}(f \text{ is a decreasing sequence from E)}\rbrakk \\
\quad \land \exists x(x \leq a \land f(0) = x) \\
\quad \land \exists \{n_j\}_j ((n_j)_j \text{ is an increasing sequence of natural numbers } \land n_0 = 0) \\
\quad \land \forall j(\phi_{[0]}(f)(j) = \text{hpt}(f(n_j))) \\
\quad \land (\phi_{[0]}(f) \text{ is a finite sequence}) \supset f \text{ is finite}, \]

where \text{hpt} is seen in Definition 1.4.

Suppose \( G_i(\phi^{[i]}, x) \) has been defined.

\[
G_{i+1}(\phi^{[i+1]}, a) : \forall x \forall \phi^{[i]}(G_i(\phi^{[i]}, x) \supset G_i(\phi^{[i+1]}(x, \phi^{[i]}), x + \omega^a)).
\]

**Note.** If we define \( G^*_i(\phi^{[i]}, a) \) to be

\[ \forall x(x \leq a \supset G_i(\phi^{[i]}, x)), \]

then it can be easily shown that

\[ G^*_i(\phi, a) \leftrightarrow G_i(\phi, a). \]

Thus, \( G_i \) can be replaced by \( G^*_i \) everywhere.

As in Section 2, we shall write \( G(i; \phi, x) \) for \( G_i(\phi, x) \) for the notational reason.

**Definition 3.3.** For each \( i, i = 0, 1, 2, \ldots, \) we define the following.

\( Pr_i(\psi^{(i)}): \forall z \forall \phi^{\langle i \rangle} \forall x(x < z \supset G(i; \phi^{\langle i \rangle})(x, x)) \supset G(i; \psi^{(i)}(x), x)) \).

\( P_i(\Psi^{(i)}): \forall x(\psi^{(i)}(Pr_i(\psi^{(i)})) \supset P_{i+1}(\Psi^{(i)}(\psi^{(i)}))). \)

Once again we write \( Pr(i; \psi) \) for \( Pr_i(\psi) \) and \( P(i; \Psi) \) for \( P_i(\Psi) \).

**Proposition 3.1.** There is a uniform (in \( i \)) method to construct primitive recursive functionals of appropriate types for \( 1 \sim 4 \) below. (See Gödel (1958), Hinata (1967), Hindley and others (1972) and Yasugi (1963) for primitive recursive functionals of finite type.)

1. \( Pr(0; \alpha_0), \) where \( \alpha_0 \) is of type \( \{0\} \).
2. \( P(i; \beta_i), \) where \( \beta_i \) is of type \( \langle i \rangle \).
3. \( Pr(i; \psi) \rightarrow G(i + 1; \gamma_i(\psi), 0), \) where \( \gamma_i \) is of type \( \{i\} \rightarrow [i + 1]. \)
4. \( Pr(i; \psi) \) and

\[ \forall \phi(G(i + 1; \phi, 0) \supset G(i + 1; \Phi(\phi), a)) \]

imply

\[ \forall \chi(G(i; \chi, 0) \supset G(i; \delta_i(\psi, \chi), \omega^a)), \]

where \( \delta_i \) is of type \( ||i|| \).
PROOF.  1. Assume
\[ \forall x (x < a \supset G(0; \phi(x), x)), \]
where \( \phi \) is of type \( \langle \langle 0 \rangle \rangle \). Let \( \alpha^* \) be the functional satisfying
\[ \alpha^*(f)(i) = f(i + 1) \]
for every \( f \) of type 1. In particular \( \alpha^*(f)(0) = f(1) \) and, if \( f \) is a decreasing sequence led by \( a \), then \( \alpha^*(f) \) is a decreasing sequence led by \( f(1) (\prec a) \). So, from the assumption,
\[ G(0; \phi(f(1)), f(1)), \]
or
\[ G(0; \phi(\alpha^*(f)(0)), \alpha^*(f)(0)), \]
and hence
\[ g: \phi(\alpha^*(f)(0))(\alpha^*(f)) \]
is a decreasing sequence of homogeneous terms satisfying the appropriate condition. Let \( \xi \) be the operation which augments \( g \) with the highest homogeneous term of \( a \), hpt(\( a \)) (see Definition 1.2), as the initial entry, in case \( g(0) < \text{hpt}(a) \) (and leaves \( g \) unchanged otherwise). Thus, define \( \alpha_0 \) to be
\[ (i) \lambda_\lambda \phi \xi(a, \phi(f(1))(\alpha^*(f))), \]
where \( \lambda \) denotes the usual \( \lambda \)-notation. From the construction,
\[ G(0; \alpha_0(a, \phi), a), \]
which, together with the assumption, implies \( Pr(0; \alpha_0) \).

2. Assume \( Pr(i; \psi) \) where \( \psi \) is of type \( \langle i \rangle \), namely,
\[ (0) \forall z \forall x(x < z \supset G(i; \chi(x), x)) \supset G(i; \psi(z, \chi), z)), \]
where \( \chi \) is of type \( \langle \langle i \rangle \rangle \). Abbreviate
\[ \forall y (y < a \supset G(i + 1; \Phi(y), y)) \]
to \( C(\Phi) \), where \( \Phi \) is of type \( \langle \langle i + 1 \rangle \rangle \). Recall that \( G(i + 1, \Phi(y), y) \) stands for
\[ \forall x \forall \phi(G(i; \phi, x) \supset G(i; \Phi(y)(x, \phi), x + \omega^\alpha)), \]
where \( \phi \) is of type \( [i] \). As before, let \( d \) be \( \text{fu}_c(b, c, a) \) and let \( n \) be \( \text{fu}_c(b, c, a) \), so
\[ b < c + \omega^\alpha \] implies \( b \leq c + \omega^\alpha n \), where \( d < a \) and \( n < \omega \). Thus, assuming
\[ b < c + \omega^\alpha, \]
\[ C(\Phi) \rightarrow G(i + 1; \Phi(d), d), \]
or
\[ C(\Phi), G(i; \phi, c) \rightarrow G(i; \Phi(d)(c, \phi), c + \omega^\alpha). \]
Define
\[ (ii) \Phi^-(0, a, b, c, \Phi, \phi) = \phi; \]
\[ \Phi^-(l + 1, a, b, c, \Phi, \phi) = \Phi(d, c + \omega^\alpha l, \Phi^-(l, a, b, c, \Phi, \phi)). \]
\( \Phi^\sim \) is of type 0, 0, 0, \( \langle \langle i + 1 \rangle \rangle \), \([i] \rightarrow [i]\). The recursion in (ii) is "uniform" in \( i \) without assuming any particular functionals. Then, more generally,

\[
C(\Phi), \ G(i; \ \Phi^\sim(i, a, b, c, \Phi, \phi), c + \omega^d l) \\
\rightarrow G(i; \ \Phi^\sim(l + 1, a, b, c, \Phi, \phi), c + \omega^d(l + 1)).
\]

Letting \( l \) be 0, 1, 2, \ldots, we obtain

\[
C(\Phi), \ G(i; \ \phi, c) \rightarrow G(i; \ \Phi^\sim(n(a, b, c), a, b, c, \Phi, \phi), c + \omega^{d(a, b, c)} n(a, b, c)).
\]

Thus,

\[
C(\Phi), \ G(i; \ \phi, c) \rightarrow \forall x(x < c + \omega^a \supset G(i; \ \Phi^\sim(n(a, x, c), a, x, c, \Phi, \phi), x)).
\]

Rewriting

\[
(\text{iii}) \quad \Phi^\star(a, x, c, \Phi, \phi) = \Phi^\sim(n(a, x, c), a, x, c, \Phi, \phi),
\]

we obtain

\[
(1) \quad C(\Phi), \ G(i; \ \phi, c) \rightarrow \forall x(x < c + \omega^x \supset G(i; \ \Phi^\star(a, x, c, \Phi, \phi), x)).
\]

In (0), let \( z \) be \( c + \omega^z \) and let \( \chi \) be \( \lambda x \Phi^\star(a, x, c, \Phi, \phi) \). Then

\[
\forall x(x < c + \omega^x \supset G(i; \ \Phi^\star(a, x, c, \Phi, \phi), x)) \\
\rightarrow G(i; \ \psi(c + \omega^x, \lambda x \Phi^\star(a, x, c, \Phi, \phi)), c + \omega^x).
\]

(1) and (2) imply

\[
C(\Phi), \ G(i; \ \phi, c) \rightarrow G(i; \ \psi(c + \omega^x, \lambda x \Phi^\star(a, x, c, \Phi, \phi)), c + \omega^x),
\]
or

\[
(3) \quad C(\Phi) \rightarrow \forall \phi \forall c(G(i; \ \phi, c) \supset G(i; \ \psi(c + \omega^x, \lambda x \Phi^\star(a, x, c, \Phi, \phi)), c + \omega^x)).
\]

Define \( \beta_i \) to be

\[
(\text{iv}) \quad \lambda \psi \lambda \alpha \lambda \Phi \lambda c \lambda \psi(c + \omega^x, \lambda x \Phi^\star(a, x, c, \Phi, \phi)).
\]

(3) will then turn to

\[
C(\Phi) \rightarrow \forall \phi \forall c(G(i; \ \phi, c) \supset G(i; \ \beta_i(\psi)(a, \Phi)(c, \phi), c + \omega^x)),
\]
or, recalling what \( C(\Phi) \) is,

\[
\forall z \forall \Phi(\forall y(y < z \supset G(i + 1; \ \Phi(y), y)) \supset G(i + 1; \ \beta_i(\psi)(a, \Phi), z)),
\]
which is \( Pr(i + 1; \ \beta_i(\psi)) \). Thus, we have established

\[
Pr(i; \ \psi) \rightarrow Pr(i + 1; \ \beta_i(\psi)),
\]

hence \( P(i; \ \beta_i) \).

Notice that \( \beta_i \) is defined uniformly in \( i \) and no induction on \( i \) is involved in the course of the proof.
3. Assume $Pr(i; \psi)$. Then, in particular,

$$\forall x(x < z + 1 \supset G(i; \chi(x), x)) \rightarrow G(i; \psi(z + 1, \chi), z + 1)$$

for any $\chi$. Suppose $G(i; \phi, z)$ holds. Then,

$$\forall x(x \leq z \supset G(i; \phi, x)).$$

Let $\chi$ be $\lambda x \phi$, so (2) becomes

$$\forall x(x < z + 1 \supset G(i; \chi(x), x)),$$

hence by (1), where $\chi$ is $\lambda x \phi$,

$$G(i; \psi(z + 1, \chi), z + \omega^0).$$

Define $\gamma_i$ by

$$\lambda \psi \lambda x \lambda \phi \psi(z + 1, \lambda x \phi).$$

Then

$$\gamma_i(\psi)(z, \phi) = \psi(z + 1, \lambda x \phi).$$

So, (3) under the assumption $G(i; \phi, z)$ yields

$$G(i; \gamma_i(\psi)(z, \phi), z + \omega^0),$$

and hence

$$\forall z \forall x(G(i; \phi, z) \supset G(i; \gamma_i(\psi)(z, \phi), z + \omega^0)), $$

which is $G(i + 1; \gamma_i(\psi), 0)$.

$\gamma_i$ is defined uniformly in $i$ without assuming any particular functionals.

4. Assume $Pr(i; \psi)$ and $\forall \phi(G(i + 1; \phi, 0) \supset G(i + 1; \Phi(\phi), a))$. The two assumptions together with 3 yield

$$G(i + 1; \Phi(\gamma_i(\psi)), a),$$

or

$$\forall x \forall \chi(G(i; \chi, x) \supset G(i; \Phi(\gamma_i(\psi))(x, \chi), x + \omega^a)).$$

Letting $x$ be 0, we obtain

$$\forall \chi(G(i; \chi, 0) \supset G(i; \Phi(\gamma_i(\psi))(0, \chi), \omega^a)).$$

Define $\delta_i$ to be

$$\lambda \psi \lambda x \lambda \phi \Phi(\gamma_i(\psi))(0, \chi).$$

This will do.

$\delta_i$ is defined uniformly in $i$, assuming the existence of $\gamma_i$, whose uniform definition has been given in (v).
PROPOSITION 3.2. There is a uniform (in i) method to construct functionals $\varepsilon_i$ and $\nu_i$ which satisfy the following.

1. $Pr(i; \varepsilon_i)$, where $\varepsilon_i$ is of type $\{i\}$.
2. $G(0; \nu_i, \omega_i)$, where $\nu_i$ is of type $\{0\}$ (for every $i$).

PROOF. 1. Define $\varepsilon_i$ by

$$\text{(vii)} \quad \varepsilon_0 = \alpha_0, \quad \varepsilon_{i+1} = \beta_i(\varepsilon_i),$$

where $\beta_i$ was defined in (iv).

(1) $Pr(0, \varepsilon_0)$

by 1 of Proposition 3.1, and

$$Pr(i; \varepsilon_i) \rightarrow Pr(i + 1; \beta_i(\varepsilon_i))$$

by 2 there, or

(2) $Pr(i; \varepsilon_i) \rightarrow Pr(i + 1; \varepsilon_{i+1}).$

(1) and repeated applications of (2) yield $Pr(i; \varepsilon_i)$ for every $i$.

Notice that, according to (vii), $\beta_j$, which was defined identically for every $j$, supplies with the mechanism to produce $\varepsilon_i$ for every $i$.

2. Define $\tau_{(i,k)}$ for $k = i + 1, i, \ldots, 0$ as follows.

$$\text{(viii)} \quad \tau_{(i,i+1)} = \iota_i, \quad \tau_{(i,k)} = \lambda \chi \delta_k(\varepsilon_k, \tau_{(i,k+1)}),$$

where $\iota_i$ is the identity of type $[i + 1] \rightarrow [i + 1]$, $\tau_{(i,k)}$ is of type $[k] \rightarrow [k]$. $\tau_{(i,k)}$ is defined uniformly in $i$ by the reversed recursion on $k$, $k = i + 1, i, \ldots, 0$, assuming the recursion mechanism of $\delta_k$ and $\varepsilon_k$. $\delta_k$ was defined in (vi) uniformly in $k$; $\varepsilon_k$ was defined in (vii) by recursion on $k$. Now,

(1) $G(i + 1; \phi, 0) \rightarrow G(i + 1; \tau_{(i,i+1)}(\phi), \omega_0)$

is a tautology. Suppose $\tau_{(i,k+1)}$ satisfies

(2) $G(k + 1; \psi, 0) \rightarrow G(k + 1; \tau_{(i,k+1)}(\psi), \omega_{i-k}).$

1 above with $i = k$, 4 of Proposition 3.1 with $i = k$, $\psi = \varepsilon_k$, $\Phi = \tau_{(i,k+1)}$ and $a = \omega_{i-k}$, and (2) above yield

$$G(k; \chi, 0) \rightarrow G(k; \delta_k(\varepsilon_k, \tau_{(i,k+1)}), \chi), \omega_{i-k+1}),$$

or

(3) $G(k; \chi, 0) \rightarrow G(k; \tau_{(i,k)}(\chi), \omega_{i-k+1}).$

(1) through (3) ensure that (3) holds for every $k$, $k = i + 1, i, \ldots, 0$. In particular,

(4) $G(0; \chi, 0) \rightarrow G(0; \tau_{(i,0)}(\chi), \omega_{i+1}),$

where $\chi$ is of type $\{0\}$. On the other hand,

(5) $G(0; I^{[0]}, 0)$
trivially holds, where $I^{[0]}$ is the identity of type $[0]$. (5) and (4) with $\chi = I^{[0]}$ yield

\[ G(0; \tau_{(i,0)}(I^{[0]}), \omega_{i+1}). \]

Define $\nu_i$ by

\[ (ix) \quad \nu_0 = I^{[0]}, \quad \nu_{i+1} = \tau_{(i,0)}(I^{[0]}). \]

Then (5) and (6) yield

\[ G(0, \nu_i, \omega_i) \]

for every $i$.

$\nu_i$ is defined from $I^{[0]}$ and $\tau_{(i,0)}$ with a simple mechanism.

**Proposition 3.3.** There are functionals which work as described below.

$ht(f)$: See Definition 1.3.

$hp(a)$: See Definition 1.4.

$\mu$: For any decreasing sequence $f$ of homogeneous terms, $\mu(f)$ is a decreasing sequence of monomials such that $\mu(f)(i)$ is a monomial in $f(m_i)$ for some $m_i$, where $\{m_i\}$ is an increasing sequence and, if $\mu(f)$ is finite, then so is $f$.

$M_h$ for each $h$ a natural number: For any decreasing sequence $f$ from $E$ such that $ht(f) = h$, $M_h(f)$ is a decreasing sequence of the highest powers of some entries of $f$, hence $ht(M_h(f)) = h - 1$, and the finiteness of $M_h(f)$ implies the same of $f$.

The types of those functionals are as follows.

$ht(f): 1 \to 0, \quad hp: 0 \to 0, \quad \mu: 1 \to 1$ and $M_h: 1 \to 1$ for all $h$.

**Proof.** $ht$ and $hp$ are easily defined.

$(x)^0 \mu(f)(0) = \text{the monomial of } f(0)$ if $f(0)$ is a homogeneous term.

Suppose $\mu(f)(0), \mu(f)(1), \ldots, \mu(f)(j)$ and $0, m_1, \ldots, m_j$ have been defined in a manner that

$(x)^j \quad \mu(f)(j) = \text{the monomial of } f(m_j)$.

Check $f(m_j + 1)$ and see if it is a homogeneous term. If so, and if $f(m_j) = \exp(\omega, a_1)n_1$ and $f(m_j + 1) = \exp(\omega, a_2)n_2$, then either $a_1 > a_2$, or $a_1 = a_2$ and $n_1 > n_2$. If the former is the case, let $m_{j+1} = m_j + 1$ and

$$\mu(f)(j + 1) = \exp(\omega, a_2).$$

If the latter is the case, check $f(m_j + 2), n_1 > n_2 > \ldots$ will stop within at most $n_1$ steps. Then $f(m_j + p) = \exp(\omega, a_{p+1})n_{p+1}$ and $a_1 > a_{p+1}$. Put $m_{j+1} = m_j + p$ and

$$(x)^{j+1} \quad \mu(f)(j + 1) = \exp(\omega, a_{p+1}).$$

$(x)^0, (x)^j$ and $(x)^{j+1}$ define $\mu$, which is primitive recursive in $f$. 

[12] Construction principle and transfinite induction

35
In case one hits a $q$ such that $f(m_j + q)$ is not a homogeneous term satisfying $f(m_j + q) < f(m_j + q - 1)$ while searching for the $p$ as above, define $\mu(f(l)) = 0$ for every $l > m_j + q$.

Next, let $\nu_h$ be the functional defined in 2 of Proposition 3.2. Define $M_h$ to be

$$(\text{xii}) \quad \lambda y(\nu_h(\mu(\nu_{h+1}(f))(j))).$$

Then by Proposition 3.2 and the properties of $\mu$ and $h\nu$, $M_h$ satisfies the condition. The construction of $M_h$ is uniform in $h$ inasmuch as that of $\nu_h$ is.

**Theorem 2.** There is a uniform method to establish that every element of $E$ is accessible with regards to $<$. 

**Proof.** The construction of $M_h$ in Proposition 3.3 is uniform in $h$ as mentioned above. Thus, define $N$ by

$$(\text{xii}) \quad N(0; f) = f, \quad N(i + 1; f) = M_{ht(f)}^{-1}(N(i; f)).$$

$N$ is of type $0, 1 \rightarrow 1$. If $f$ is any decreasing sequence from $E$, then $N(ht(f); f)$ is a decreasing sequence of height $0$, which is infallibly finite; according to the definition of $M_h$, the finiteness of $N(ht(f); f)$ implies the same of $f$. Thus, $f$ must be finite. This proves that every element of $E$ is $<$-accessible.

$N(i; f)$ is defined by recursion on $i$, whose mechanism is provided by the construction of $M_h$, which in turn depends on $\nu_h$.

**Speculation.** In (i) through (xii), we have defined functionals for each set of values of parameters, $i, k, \ldots$. Thus, let $S_i$ denote the functional for $i$. We can regard $\{S_i\}_i$ as an enumeration of some functionals, which we write as $S$. From a reversed view point, $S$ can be regarded as an object, or a construction principle, which produces individual $S_i$'s as instances of it. It is such an $S$ we are to characterize in the subsequent sections.

**4. Construction principle**

Here we shall formulate the construction principle, which was announced in the preceding section.

**Definition 4.1.** 1) Symbols.

1.1) $\mathcal{A}, \mathcal{B}, \ldots$ : parameters.

1.2) $f, g, \ldots$ : a finite list of unary function symbols.

1.3) $p, q, \ldots$ : a finite list of function symbols (distinct from those of 1.2)).

1.4) $P, Q, \ldots$ : a finite list of predicate symbols.
2) Pre-types.
2.1) A function symbol (in 1.2)) accompanied by a parameter is a pre-type.
2.2) A finite type (denoted by 0, s, t, etc.) is a pre-type (see Definition 3.1).
2.3) If \( \eta \) and \( \iota \) are pre-types, then so is \( \eta \rightarrow \iota \).

3) Pre-variables. For each pre-type \( \eta \), there are assumed to be denumerably many pre-variables \( \phi^\eta, \psi^\eta, \ldots \).

4) Pre-terms and free and bound occurrences of parameters.
4.1) Pre-variables are pre-terms; the parameters in their superscripts (pre-types) are free.
4.2) Primitive recursive terms of finite type (see Gödel (1958), Hinata (1967), Hindley and others (1972), Yasugi (1963)) are pre-terms; there are no parameters here.
4.3) If \( X \) and \( Y \) are pre-terms, then so is \( X(Y) \); the free occurrences of parameters in \( X(Y) \) are exactly those in \( X \) or \( Y \), and the bound occurrences likewise.
4.4) If \( X \) is a pre-term and \( \phi \) is a pre-variable which is free in \( X \), then \( \lambda \phi X \) is a pre-term; the free occurrences of parameters in it are exactly those in \( \phi \) or \( X \), and the bound occurrences likewise.
4.5) If \( P_1, \ldots, P_m \) are predicate symbols accompanied by appropriate numbers of parameters and \( X_1, \ldots, X_m, X_{m+1} \) are pre-terms, then \( C[P_1, \ldots, P_m, X_1, \ldots, X_m, X_{m+1}] \) is a pre-term; the free occurrences of parameters in it are those in any of \( P_1, \ldots, P_m, X_1, \ldots, X_m, X_{m+1} \), and the bound ones likewise.
4.6) If \( X \) and \( Y \) are pre-terms which are free of \( R \), then \( \rho[X, Y] \) is a pre-term. The free parameters are those in one of \( X \) and \( Y \), and the bound ones likewise.
4.7) If \( X \) and \( Y \) are pre-terms, where \( \alpha \) does not occur free in \( X \), then \( R[\alpha; X, Y] \) is a pre-term. The free occurrences of parameters are \( \alpha \) and those in \( X \) or \( Y \); the bound ones are those in \( X \) or \( Y \).
4.8) If \( X \) is a pre-term, \( \mathcal{C}_1, \ldots, \mathcal{C}_l \) are some of the free parameters in \( X \) and \( P_1, \ldots, P_l \) are auxiliary function symbols accompanied by some parameters which are not among \( \mathcal{C}_1, \ldots, \mathcal{C}_l \) and not bound in \( X \), then \( \text{Sub}(X; \mathcal{C}_1, \ldots, \mathcal{C}_l) \) is a pre-term. The free parameters in \( X \) which are distinct from \( \mathcal{C}_1, \ldots, \mathcal{C}_l \) and the parameters in \( P_1, \ldots, P_m \) are free in the new pre-term. The bound ones are those in \( X \) and \( \mathcal{C}_1, \ldots, \mathcal{C}_l \).

**Definition 4.2.** Functional specification.
1) A type function is a primitive recursive function (of one or several arguments) which enumerates some finite types.
2) Let \( \mathcal{F} \) be a finite list of unary type functions corresponding to function symbols in 1.2) of Definition 4.1.
Let $\mathcal{P}$ be a finite list of primitive recursive functions corresponding to auxiliary function symbols in Definition 4.1. Those will be called auxiliary functions.

Let $\mathcal{B}$ be a finite set of primitive recursive predicates corresponding to predicate symbols in Definition 4.1. Those will be called case-predicates.

3) The functional specification (with regards to $(\mathcal{F}, \mathcal{P}, \mathcal{B})$) of any symbol defined in 1.2) ~ 1.4) of Definition 4.1 is obtained from it by specifying it by the corresponding object from $\mathcal{F}$, $\mathcal{P}$ and $\mathcal{B}$.

4) For a pre-type $\mathfrak{s}$, the functional specification of $\mathfrak{s}$ is defined as follows. If $\mathfrak{s}$ is a function symbol accompanied by a parameter, then its specification is the corresponding function from $\mathcal{F}$, regarding the parameter as the variable. If $\mathfrak{s}$ is a finite type, then $\mathfrak{s}$ is itself its own specification. Suppose the specifications of $\mathfrak{s}$ and $\mathfrak{t}$ are respectively primitive recursive functions $f$ and $g$ of several parameters, then the specification of $\mathfrak{s} \to \mathfrak{t}$ is a function of $m$ variables $h$ such that for each set of values of parameters, say $k$, $h(k) = f(k) \to g(k)$. We write $f \to g$ for $h$.

Note. Various properties of primitive recursive functions and predicates which are presumed in the definitions are supposed to be provable in primitive recursive arithmetic.

**Definition 4.3.** 1). Let $F$ be the functional specification of any symbol from 1.2) ~ 1.4) of Definition 4.1 accompanied by some parameters (see 3) of Definition 4.2), and let $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ be some parameters. Then

$$\operatorname{Spec}(F; \mathfrak{B}_1; \ldots; \mathfrak{B}_m)$$

will denote the substitution in $F$ of numbers $k_1, \ldots, k_m$ for $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ respectively. We call this a numerical specification of $F$. If $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ exhaust all the parameters in $F$, then we say that it is a complete (numerical) specification of $F$.

2) The numerical specification defined in 1) above induces the numerical specification of the functional specification of a pre-type, which represents a finite type. It will be denoted as in 1).

3) Let $\phi^s$ be a pre-variable and let $F$ be the functional specification of $\mathfrak{s}$. Then $\phi^F$ will be called a variable of the type function $F$. If $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ exhaust the parameters occurring in $F$, then $G \equiv \operatorname{Spec}(F; \mathfrak{B}_1; \ldots; \mathfrak{B}_m)$, a complete (numerical) specification of $\phi^F$, is defined to be $\phi^G$. Notice that $G$ is a finite type, hence there is a pre-variable $\phi^G$, which is regarded also as a variable of type $G$.

4) Let $X$ be the functional specification of a pre-term, where $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ exhaust the free parameters in $X$. A complete numerical specification of $X$, $\operatorname{Spec}(X; \mathfrak{B}_1; \ldots; \mathfrak{B}_m)$, is defined according to the construction in 4) of Definition 4.1.
4.1) Spec($\phi^F; \rho_1 \cdots \rho_m$) has been defined in 3) above.

4.2) Terms of finite type are not affected by specifications.

4.3) Spec($X(Y); \rho_1 \cdots \rho_m$) $\equiv$ Spec($X; \rho_1 \cdots \rho_m$(Spec($Y; \rho_1 \cdots \rho_m$)).

4.4) Spec($\lambda\phi X; \rho_1 \cdots \rho_m$) $\equiv$ $\lambda$Spec($\phi; \rho_1 \cdots \rho_m$)Spec($X; \rho_1 \cdots \rho_m$).

4.5) Spec($C[P_1, \ldots, P_l, X_1, \ldots, X_l, X_{l+1}]; \rho_1 \cdots \rho_m$)

$\equiv$ C[$\sigma P_1, \ldots, \sigma P_l, \sigma X_1, \ldots, \sigma X_l, \sigma X_{l+1}$],

where $\sigma Y$ abbreviates Spec($Y; \rho_1 \cdots \rho_m$).

4.6) Spec($\rho[X, Y]; \rho_1 \cdots \rho_m$) $\equiv$ Spec($X; \rho_1 \cdots \rho_m$), Spec($Y; \rho_1 \cdots \rho_m$).

4.7) Spec($R[\emptyset, X, Y]; q \rho_1 \cdots \rho_m$)

$\equiv$ Spec($X; \rho_1 \cdots \rho_m$);

Spec($R[\emptyset, X, Y]; q \rho_k \cdots \rho_m$)

$\equiv$ Spec($Y; q \rho_1 \cdots \rho_m$)(Spec($R[\emptyset, X, Y]; q \rho_k \cdots \rho_m$)).

4.8) Spec(Sub($X; \rho_1 \cdots \rho_k$); $\rho_1 \cdots \rho_m$)

$\equiv$ Spec($X; \rho_1 \cdots \rho_m \rho_1 \cdots \rho_t$),

where $p_i$ denotes the functional specification of an auxiliary function symbol and $\sigma p_i$ $\equiv$ Spec($p_i; \rho_1 \cdots \rho_m$) (see 2) above).

Since the parameters in $p_1, \ldots, p_t$ are not among $\rho_1, \ldots, \rho_t$, the definition is consistent.

**PROPOSITION 4.1.** The definition immediately above is complete.

**PROOF.** By induction on the construction of pre-terms, within which by induction on $k$ in 4.7).

**DEFINITION 4.4.** Term-forms and the associated type functions.

The functional specification of a pre-term is a term form in the subsequent circumstances. We quote 4) of Definition 4.1.

4.1) A variable is a term-form; the associated type function is the type function in 3) of Definition 4.3.

4.2) A term is a special case of the term-form and its type is a special case of the type function.

4.3) The type function of $X$ is of the form $f \rightarrow g$ and that of $Y$ is $f$. The type function of $X(Y)$ is $g$.

4.4) If $\phi$ is a variable of type function $f$ and $X$ is a term-form of $g$, then $\lambda\phi X$ is a term-form of $f \rightarrow g$. 
4.5) If $P_1, \ldots, P_m$ are mutually exclusive predicates and $X_i$ is a term-form of type function $f_i, i = 1, \ldots, m + 1$, then $C[P_1, \ldots, P_m; X_1, \ldots, X_m, X_{m+1}]$ is a term-form of type function

$$n(x_1)f_1 + \cdots + n(x_m)f_m + x_1 \cdots x_m f_{m+1},$$

where $x_i$ is the characteristic function of $P_i$ and $n(x_i)$ represents its reciprocal signum.

4.6) If $X$ is a term-form of $f$, then $Y$ is one of $0 \rightarrow (f \rightarrow f)$. $\rho[X, Y]$ is a term-form of $0 \rightarrow f$.

4.7) Let $f$ and $g$ be type functions of term-forms $X$ and $Y$ respectively, where $\mathfrak{a}, \mathfrak{b}_1, \ldots, \mathfrak{b}_m$ exhaust all the free parameters of $f$ and $g$. Suppose for a type function $h$ with parameters $\mathfrak{a}, \mathfrak{b}_1, \ldots, \mathfrak{b}_m$,

$$h(0, k_1, \ldots, k_m) = f(k_1, \ldots, k_m),$$
$$g(k, k_1, \ldots, k_m) = h(k, k_1, \ldots, k_m) \rightarrow h(k + 1, k_1, \ldots, k_m)$$

for every set of $k, k_1, \ldots, k_m$ (values of $\mathfrak{a}, \mathfrak{b}_1, \ldots, \mathfrak{b}_m$). Then $R[\mathfrak{a}, X, Y]$ is a term-form of type function $h$.

4.8) Suppose $X$ is a term-form of type function $f(\mathfrak{a}_1, \ldots, \mathfrak{a}_n, \mathfrak{c}_1, \ldots, \mathfrak{c}_l)$. Then $\text{Sub}(X; \mathfrak{a}_1, \ldots, \mathfrak{a}_n)$ is a term-form of type function

$$f(\mathfrak{a}_1, \ldots, \mathfrak{a}_n, p_1, \ldots, p_l)$$

whose parameters are $\mathfrak{a}_1, \ldots, \mathfrak{a}_n$ and those in $p_1, \ldots, p_l$.

**Corollary.** A term-form and its associated type function share the same free parameters, and a finite type is associated with a complete specification of a term-form.

**Principle.** The term-form is what we claim to be a construction principle, since it is designed to enumerate some primitive recursive functionals, possibly of different types.

**Definition 4.5. Reduction.** For a term-form $X$ of associated type function $f(\mathfrak{b}_1, \ldots, \mathfrak{b}_m)$,

$$\sigma X \equiv \text{Spec}(X; \mathfrak{b}_1, \ldots, \mathfrak{b}_m)$$

(a complete numerical specification) can be said of type $f(k_1, \ldots, k_m)$. $X, Y, \ldots$ will denote term-forms, $\sigma X, \sigma Y, \ldots$ their complete specifications (without explicitly specifying the numbers unless necessary) and $U, V, \ldots$ some primitive recursive terms of finite type.

$\sigma X \Rightarrow U$ will express the fact that $U$ is the reduct of $X$, where $\sigma X$ and $U$ share a common finite type. Reducts will be defined so that, if a variable $\phi_i(\mathfrak{b}_1, \ldots, \mathfrak{b}_m)$
occurs in $X$, then $\phi_i^{(k_1, \ldots, k_m)}$ occurs in $U$, and no new variables are introduced. The definition of reducts will be given according to the construction of pre-terms in 4) of Definition 4.1.

4.1) Consider a pre-variable $\phi^s_i$, where $s$ is a pre-type, and let $s$ be a complete specification of $s$. More precisely, $s$ is the result of computation of a specification. $s$ represents a finite type, hence $\phi^s_i$ exists among the variables of finite type. Now

$$\sigma \phi \Rightarrow \phi^s_i.$$ 

4.2) $X \Rightarrow X$ if $X$ is a primitive recursive term of finite type, since $\sigma X \equiv X$.

4.3) If $\sigma X \Rightarrow U$ and $\sigma Y \Rightarrow V$, then

$$\sigma(X\langle Y \rangle) \equiv \sigma X\langle \sigma Y \rangle \Rightarrow U\langle V \rangle,$$

where $U\langle V \rangle$ represents the application of $U$ to $V$ in the usual sense.

4.4) If $\sigma \phi \Rightarrow \psi$ and $\sigma X \Rightarrow U$, then

$$\sigma(\lambda \phi X) \equiv \lambda \sigma \phi \sigma X \Rightarrow \lambda \psi U,$$

where the last $\lambda$ represents the usual $\lambda$-notation.

4.5) Suppose $\sigma X_i \Rightarrow U_i$, $i = 1, \ldots, m + 1$. Then

$$\sigma C[P_1, \ldots, P_m, X_1, \ldots, X_m, X_{m+1}]$$

$$\equiv C[\sigma P_1, \ldots, \sigma P_m, \sigma X_1, \ldots, \sigma X_m, \sigma X_{m+1}]$$

$$\Rightarrow n(X_1)U_1 + \cdots + n(X_m)U_m + X_1 \ldots X_m U_{m+1},$$

where $X_i$ and $n(X_i)$ were defined in Definition 4.4 and the reduct is defined in the arithmetic of primitive recursive terms of finite type. $X_i$ here in fact represents either 0 or 1, since we are dealing with a complete specification.

4.6) If $\sigma X \Rightarrow U$ and $\sigma Y \Rightarrow V$, then

$$\sigma p [X, Y] \equiv p[\sigma X, \sigma Y] \Rightarrow p[U, V],$$

where the last $p$ is interpreted to be the recursion operator.

4.7) Suppose $\text{Spec}(X; \mathfrak{B}) \Rightarrow U$ and $\text{Spec}(Y; \mathfrak{B}_k) \Rightarrow W$. (We have written out just one parameter $\mathfrak{B}$ for simplicity.) Then

$$\text{Spec}(R[\mathfrak{A}, X, Y]; \mathfrak{B}_k) \equiv \text{Spec}(X; \mathfrak{B}) \Rightarrow U,$$

$$\text{Spec}(R[\mathfrak{A}, X, Y]; \mathfrak{B}_{k+1})$$

$$\equiv \text{Spec}(Y; \mathfrak{B}_k) \langle \text{Spec}(R[\mathfrak{A}, X, Y]; \mathfrak{B}) \rangle \Rightarrow W \langle V \rangle,$$

where $\text{Spec}(R[\mathfrak{A}, X, Y]; \mathfrak{B}_k) \Rightarrow V$.

4.8) Let $X$ be a term-form where $\mathfrak{B}_1, \ldots, \mathfrak{B}_m$ cover all the free parameters distinct from $C_1, \ldots, C_i$ and those in $p_1, \ldots, p_i$. Suppose

$$\text{Spec}(X; \mathfrak{B}_1 \cdots \mathfrak{B}_m \mathfrak{C}_1 \cdots \mathfrak{C}_l) \Rightarrow U,$$
where $r_l = \text{Spec}(p_l; k_1 \cdots k_m)$. Then

$$\text{Spec}(\text{Sub}(X; c_1 \cdots c_p); k_1 \cdots k_m) \Rightarrow U.$$

If $\alpha X \Rightarrow U$, then we say that $\alpha X$ reduces to $U$ or $\alpha X$ is reducible to $U$. If every complete specification of a term-form $X$ is reducible (to a primitive recursive term of finite type), then we say that $X$ is reducible.

**Theorem 3.** Every term-form is reducible.

**Proof.** By induction on the construction of a term-form, within which by induction on $l$. We have only to examine each case in Definition 4.5; consult also Definitions 4.3 and 4.4.

**Conclusion.** Our construction principle—term-forms—is computable, in the sense that every term-form is reducible, namely every complete specification of a term-form is reduced to a primitive recursive term of finite type, which is considered to be computable.

*Note.* As for the computability of primitive recursive functionals of finite type, see for example Diller (1968), Hinata (1967) and Hindley and others (1972).

The demonstration of the computability of our construction is based on the soundness of the system of primitive recursive functionals of finite type and the double induction used in Theorem 3 above.

## 5. Functional interpretation concluded

Now we shall show that the functional construction in Section 3 can be interpreted in terms of the construction principle in Section 4. We first build up a term-form that corresponds to the functional $N$ in Theorem 2 of Section 3, following the procedure in (i) ~ (xii) there, and then demonstrate that it does the work.

**Definition 5.1.**

1) We specify the type functions, auxiliary functions and auxiliary predicates, $(\gamma, p, \Psi)$, in Definition 4.2 (see also Definition 3.1).

$$\gamma: \{a\}, \{a + 1\}, \langle\langle a\rangle\rangle, \{a\}, \langle a\rangle, \|a\|.$$  

$p: a + 1, (\beta + 1) \div a, a \div a.$  

$$\Psi: a = \beta + 1, (\beta - 1) \div a > 0.$$  

2) Construction. For any object $S$ which was defined in (i) ~ (xii), Section 3, we let $T(S)$ denote the term-form which is to be defined corresponding to it. (Review the note at the end of Section 3.)
(i)* The $\alpha_0$ in (i) is a primitive recursive functional of finite type. Let $T(\alpha_0)$ be
$\alpha_0$ itself.

(ii)* Let $T(\Phi^-)$ be
$$\rho \left[ [\Phi]_{\alpha}, \lambda \Phi \phi + 1 \langle d, c + \omega d \rangle \right],$$
where $d = d \langle a, b, c \rangle$ and $a, b, c, \phi, \Phi$ are variables. Notice that $R$ is not
involved.

(iii)* $T(\Phi^*) \equiv T(\Phi^-) \langle n \langle a, x, c \rangle \rangle$.

(iv)* $T(\beta) \equiv \lambda \psi \lambda \Phi \lambda c \lambda \Phi \psi \langle c + \omega, \lambda x T(\Phi^*) \rangle$,
where the associated type functions are as follows.

(v)* $T(\gamma) \equiv \lambda \psi \lambda z \lambda \Phi \psi \langle z + 1, \lambda x \phi \rangle$,
where the associated type functions are \{\$\} for \$ and \{\$\} for \$.

(vi)* $T(\delta) \equiv \lambda \psi \lambda \Phi \lambda \chi \phi \langle \gamma \langle \psi \phi \rangle, 0, \chi \rangle$,
\{\$\} for $\psi$, \{\$ + 1\}, 0, \{\$\} $\rightarrow$ \{\$\} for $\Phi$ and \{\$\} for $\chi$.

(vii)* $T(\epsilon) \equiv R[\langle \epsilon \rangle, T(\alpha_0), T(\beta)]$.

(viii)* Here we need some auxiliary steps.
Define $f(\beta)$ to be \[\beta + 1 \rightarrow [\beta + 1] \] and $I^{R(\beta)}$ to be $\lambda \eta \cdot \eta$, where $\eta$ has the
type function \[\beta + 1 \]. Define further:

$$\Theta \equiv \lambda \phi \alpha, \quad \text{for } \phi \text{ of type } ||0||,$$
$$Z \equiv \text{Sub}(T(\delta)\langle T(\epsilon) \rangle; (\beta + 1) \langle \alpha \rangle),$$
$$Y \equiv C[\langle \beta + 1 \rangle \langle \epsilon \rangle C \geq 0, Z, \Theta].$$

Then

$$T(\tau) \equiv R[\alpha, I^{R(\beta)}, Y].$$

(ix)* $T(\nu) \equiv C[\beta] = 0, I^{[0]}, \text{Sub}(\tau^-; \beta), I^{[0]}],$
where $I^{[0]}$ is the identity of type $[0]$, and

$$\tau^- \equiv \text{Sub}(T(\tau); \beta + 1) \langle I^{[0]} \rangle.$$

(x)* $\mu$ is a term of finite type; $T(\mu) \equiv \mu$.

(xi)* $T(M) \equiv \lambda \mu \lambda \phi \lambda f \langle \mu \langle \text{Sub}(T(\nu); \beta + 1) \rangle \rangle \langle f \rangle \langle j \rangle$.

(xii)* $T(N) \equiv R[\beta, f, M^-],$
where

$$M^- \equiv \text{Sub}(T(M); \beta + 1).$$

Proposition 5.1. The expressions defined in (i)* $\sim$ (xii)* are legitimate term-
forms.
PROPOSITION 5.2. For any \( f_0 \) a decreasing sequence from \( E \) and a number \( i \),

\[
\text{Spec}(T(N); \begin{smallmatrix} g \\ \in(f_0) \end{smallmatrix} i)
\]

acts as the \( N(i; f_0) \) in (xii).

PROOF. We shall show that for each term-form \( T(S) \) in one of (i)* \( \sim \) (xii)* above, any of its complete specification is reduced to the term which is obtained from \( S \) by instantiating it by the same set of values of parameters. See Definitions 4.3 and 4.5 for evaluation.

(i) Obvious.

(ii) \( \text{Spec}(T(\Phi^\sim); i) \equiv \rho[\text{Spec}(\phi[i^\sim]; i), \text{Spec}(\lambda i \Phi[i^\sim+1]<d', c + \omega^d>); i] \)

\[
\Rightarrow \rho[\phi[i^\sim], \lambda i \Phi[i^\sim+1]<d', c + \omega^d>],
\]

which represents the \( \Phi^\sim_i \) in (ii) according to the interpretation of \( \rho \) as the recursion operator of functionals (see Yasugi (1963)).

(iii) \( \sim \) (vi) are dealt with likewise. Let us consider (iv) as an example.

(iv) \( \text{Spec}(T(\beta); i) \)

\[
\equiv \lambda \text{Spec}(\psi; i) \lambda \text{Spec}(\Phi; i) \lambda \text{Spec}(\phi; i)
\]

\[
\text{Spec}(\psi; i) = c + \omega^a, \lambda x \text{Spec}(T(\Phi^*); i)
\]

\[
\Rightarrow \lambda \psi = \lambda \text{Spec}(\Phi^*), \lambda x \text{Spec}(\phi^*),
\]

where \( \text{Spec}(T(\Phi^*); i) \equiv \Phi^* \) by (iii), \( s \equiv 0, (0 \rightarrow [i]) \rightarrow [i] \) and \( i \equiv 0 \rightarrow [i + 1] \).

(vii) We prove this case by induction on \( i \).

\[
\text{Spec}(R[\begin{smallmatrix} \varnothing \\ \in(i) \end{smallmatrix}, T(\alpha_0), T(\beta)]; i) \equiv \alpha_0 \equiv \epsilon_0.
\]

Suppose

\[
\text{Spec}(R[\begin{smallmatrix} \varnothing \\ \in(i) \end{smallmatrix}, T(\alpha_0), T(\beta)]; i+1) \Rightarrow \epsilon_i
\]

has been established.

\[
\text{Spec}(R[\begin{smallmatrix} \varnothing \\ \in(i+1) \end{smallmatrix}, T(\alpha_0), T(\beta)]; i+1) \equiv \text{Spec}(T(\beta); i) \text{Spec}(R[\begin{smallmatrix} \varnothing \\ \in(i) \end{smallmatrix}, T(\alpha_0), T(\beta)]; i+1) \Rightarrow \beta_i \epsilon_i \equiv \epsilon_{i+1}
\]

by (iv) and the induction hypothesis.

(viii) \( \text{Spec}(Z; i_k) \equiv \text{Spec}(T(\delta); i_k) \equiv \text{Spec}(T(\delta); i_k) \equiv \delta_{i_k} \epsilon_{i+k}
\]

\[
\Rightarrow \delta_{i+k} \epsilon_{i+k}
\]

by (vi) and (vii).
\[
\text{Spec}(Y; \bar{\beta} \bar{\gamma}) \equiv C[ \text{Spec}(\bar{\beta} \bar{\gamma} + 1 \div \bar{\beta} > \bar{\gamma} 0; i \bar{\beta} \bar{\gamma}) , \text{Spec}(Z; \bar{\beta} \bar{\gamma}), \text{Spec}(\Theta; \bar{\beta} \bar{\gamma}) ]
\]
\[
\Rightarrow n(\chi(l, k))\delta_{(l+1)^{-k}} \langle \varepsilon_{(l+1)^{-k}, k} \rangle + \chi(l, k)\Theta,
\]

where \(\chi(l, k)\) is the characteristic function of \((l + 1) \div k > 0\). Thus, if \(k < l + 1\), then the reduct is

\[
\delta_{(l+1)^{-k}} \langle \varepsilon_{(l+1)^{-k}, k} \rangle.
\]

\[
\text{Spec}(T(\tau); \bar{\beta} \bar{\gamma}) \equiv I^{(l)} \Rightarrow I_j \equiv \tau_{(l,l+1)}.
\]

Suppose \(k < l\) and

\[
\text{Spec}(T(\tau); \bar{\beta} \bar{\gamma}) \Rightarrow \tau_{(l,l+1)^{-k}}.
\]

Then

\[
\text{Spec}(T(\tau); \bar{\beta} \bar{\gamma}) \equiv \text{Spec}(Y; \bar{\beta} \bar{\gamma}) \langle \text{Spec}(T(\tau); \bar{\beta} \bar{\gamma}) \rangle
\]
\[
\Rightarrow \delta_{(l+1)^{-k}} \langle \varepsilon_{(l+1)^{-k}, k} \rangle \langle \tau_{(l,(l+1)^{-k})} \rangle
\]
\[
\equiv \tau_{(l,(l+1)^{-k}(l+1))}.
\]

(ix) \(\text{Spec}(T(\tau^-); \bar{\beta} \bar{\gamma}) \equiv \text{Spec}(T(\tau); \bar{\beta} \bar{\gamma}) \langle \text{Spec}(I^{[0]}, \bar{\beta} \bar{\gamma}) \rangle \Rightarrow \tau_{(l,0)} \langle I^{[0]} \rangle
\]
by (viii) where \(k = l + 1\).

(x) \(\text{Spec}(T(\nu); \bar{\beta} \bar{\gamma}) \equiv C[ \text{Spec}(\bar{\beta} = 0; \bar{\gamma}), I^{[0]}, \text{Spec}(T(\tau^-); i \bar{\beta} \bar{\gamma}) ]
\]
\[
\Rightarrow n(\chi(i = 0))I^{[0]} + \chi(i = 1)\tau_{(l-1,0)} \langle I^{[0]} \rangle
\]
\[
\equiv \begin{cases} I^{[0]} \equiv \nu_0 & \text{if } i = 0, \\
\tau_{(l,0)}(I^{[0]}) \equiv \nu_i & \text{if } i = j + 1. \end{cases}
\]

(xi) \(\text{Spec}(T(M); \bar{\delta} \bar{\beta}) \equiv \lambda \mu \langle \text{Spec}(T(\nu); h_{i+1} \bar{\delta}) \rangle \langle f \rangle \langle j \rangle
\]
\[
\Rightarrow \lambda \mu \langle \text{Spec}(T(\nu+1) \langle f \rangle \langle j \rangle
\]
by (x).

(xii) Let \(ht(f_0)\) be \(j\).

\[
\text{Spec}(M^{-}; \bar{\delta} \bar{\beta}) \equiv \text{Spec}(T(M); i j j \bar{\delta} \bar{\gamma})
\]
\[
\equiv \text{Spec}(T(M); j \bar{\delta} \bar{\gamma})
\]
\[
\Rightarrow M_{j-i}
\]
by (xi).

\[
\text{Spec}(T(N); \bar{\delta} \bar{\beta}) \Rightarrow f_0.
\]
Suppose $i < j$ and

$$\text{Spec}(T(N); \frac{\varphi}{i, j}) \Rightarrow N(i; f_0).$$

Then

$$\text{Spec}(T(N); i_{i+1, j}) \equiv \text{Spec}(M \sim; i_{i, j}) \langle \text{Spec}(T(N); \frac{\varphi}{i, j}) \rangle$$

$$\Rightarrow M_{j-i}(N(i; f_0)) \equiv N(i + 1; f_0).$$

This completes the proof of the proposition.

**CONCLUSION.** The functional construction which the accessibility proof of $(E, \prec)$ in Section 3 is based upon can be interpreted in the theory of term-forms.
