Social Cognition and Behavioral Variant of Frontotemporal Dementia: Evaluative Utility for the Health and Forensic Field

Martin J. Mazzoglio y Nabar, MD, MSc, Emmanuel E. Leidi Terren, MD, MSc and Daniel H. Silva, MD, PhD

Abstract

Introduction. The behavioral variant of frontotemporal dementia presents clinical specificities and difficulties for its early diagnosis in the initial stages due to the overlap of symptoms with other psychiatric pathologies. The delay in diagnosis places the subject in a state of vulnerability because the treatment will not be adequate and the alteration in the psycho-functional capacity can expose him to risks.

Efficacy, Tolerability, and Safety of Atypical Antipsychotics in East Asian Ethnicity

Mehwish Hina, MD, Tania Sultana, MD and Sophia Youn

Department of Psychiatry, Bergen New Bridge Medical Center, Paramus, NJ, USA

Abstract

Background. A number of intrinsic (age, gender, physical comorbidities, genetic factors, and ethnicity), and extrinsic factors (diet, concomitant medications, alcohol use, and smoking) influence an individual’s response to psychotropic medications. Data suggest that ethnicity may affect medication efficacy, tolerability, and safety through different pharmacokinetics and pharmacodynamics. Asians have been found to have a high frequency of reduced function of CYP2D6 allele (CYP2D6*10), which contributes to the slower metabolism of some medications compared to other ethnic groups for efficacy, safety, and adverse effects, although they can cause serious and undesirable side effects.

Objective. The objective of this research was to describe the importance of the forensic and health level of the neuropsychological evaluation of social cognition in people with behavioral variant frontotemporal dementia and to correlate the results with the clinical manifestations of the patients.

Materials and Methods. Forty-five patients with behavioral variant frontotemporal dementia were studied with social cognition tests (Reading the Mind in the Eyes and Faux Pas Tests) and staged with standardized scales (CDR [Clinical Dementia Rating], GDS [Global Deterioration Scale], and the FTD-FRS [Frontotemporal Dementia Rating Scale]). The results were analyzed with descriptive and inferential statistical tests and the current ethical-legal requirements were met (requirement of informed consent, reservation of the identity of the participants, compliance with the GCP-Good clinical practice-, ANMAT provision 6677/10 and adherence to the Ethical Principles derived from the Declaration of Helsinki).

Results. We found a significant prevalence of alterations in social cognition tests, mainly in Faux Pas Test, from the initial stages of the disease, which were correlated with the clinical stage of the patient.

Conclusions. The behavioral variant of frontotemporal dementia is a condition with significant diagnostic complexity in its initial stages that affects decision-making, the type of treatment to be instituted and presents the consequences for the subject and their environment. Early detection with a deep assessment of social tools will provide clinical tools for pharmacological treatment, as well as to know the capacity and safeguard the rights of the subject and implement the necessary support measures. It was confirmed that the alterations in the social cognition tests were correlated with the clinical stage in the FTD-FRS scale and high implication in the results of the Faux Pas Test mainly, and secondarily in the Reading the Mind in the Eyes Test.
