NAOTO MIYOSHI,*** Tokyo Institute of Technology

Abstract

We study the multi-selection version of the so-called odds theorem by Bruss (2000). We observe a finite number of independent 0/1 (failure/success) random variables sequentially and want to select the last success. We derive the optimal selection rule when \( m \geq 1 \) selection chances are given and find that the optimal rule has the form of a combination of multiple odds-sums. We provide a formula for computing the maximum probability of selecting the last success when we have \( m \) selection chances and also provide closed-form formulae for \( m = 2 \) and 3. For \( m = 2 \), we further give the bounds for the maximum probability of selecting the last success and derive its limit as the number of observations goes to \( \infty \). An interesting implication of our result is that the limit of the maximum probability of selecting the last success for \( m = 2 \) is consistent with the corresponding limit for the classical secretary problem with two selection chances.

Keywords: Optimal stopping; selecting the last success; multiple selection chances

1. Introduction

For a positive integer \( N \), let \( X_1, X_2, \ldots, X_N \) denote independent 0/1 random variables defined on a probability space \((\Omega, \mathcal{F}, P)\). We observe these \( X_i \)s sequentially and claim that the \( i \)th trial is a success if \( X_i = 1 \). The problem lies in finding a rule \( \tau \in \mathcal{T} \) to maximize the probability of selecting the last success, where \( \mathcal{T} \) is the class of all selection rules such that \( \{\tau = j\} \in \sigma(X_1, X_2, \ldots, X_j) \), that is, the decision of whether to select the \( j \)th success depends on the information up to \( j \). Let \( \mathcal{N} = \{1, 2, \ldots, N\} \), and let \( p_i = P(X_i = 1) \) and \( q_i = 1 - p_i = P(X_i = 0) \) for \( i \in \mathcal{N} \). In addition, let \( r_i, i \in \mathcal{N}, \) denote the odds of the \( i \)th trial; that is, \( r_i = p_i/q_i \), where we set \( r_i = +\infty \) if \( p_i = 1 \). When exactly one selection chance was allowed, Bruss [3] solved the problem with elegant simplicity as follows.

Proposition 1.1. (Theorem 1 of [3].) Suppose that exactly one selection chance is given in the problem above. Then, the optimal selection rule \( \tau^{(1)}_* \) selects the first success after the sum of

the future odds becomes less than 1; that is
\[
  r_i^{(1)} = \min\{i \geq i^{(1)}_i : X_i = 1\},
\]
\[
  i^{(1)}_i = \min\left\{ i \in \mathcal{N} : \sum_{j=1}^{N} r_j < 1 \right\},
\]
where \( \min(\varnothing) = +\infty \) and \( \sum_{j=a}^{b} \cdot = 0 \) when \( b < a \) conventionally. Furthermore, the maximum probability of ‘win’ (selecting the last success) is given by
\[
  P^{(1)}(\text{win}) = P^{(1)}_N(p_1, \ldots, p_N) = \prod_{k=1}^{\infty} q_k \sum_{k=1}^{\infty} r_k.
\]

This result, referred to as the sum-the-odds theorem, or the odds theorem for short, is attractive because it can be applied to many basic optimal stopping problems, such as betting, the classical secretary problem (CSP), and the group-interview secretary problem proposed by Hsiau and Yang [11]. Bruss [3] also proved that \( P^{(1)}(\text{win}) \) in (1.3) is bounded below by \( R^{(1)}e^{-R^{(1)}} \) with \( R^{(1)} = \sum_{j=1}^{N} r_j \). Remarkably, in [4], he found that it is bounded below by \( e^{-1} \) when \( \sum_{j=1}^{N} r_j \geq 1 \). These results generalize the known lower bounds for the CSP, where each \( p_i \) has the specific value of \( p_i = 1/i \) for \( i \in \mathcal{N} \) (see, e.g. [10]).

After Bruss [3], which includes the problem with a random number of observations, the odds theorem has been extended in several directions. Bruss and Paindaveine [5] extended it to the problem of selecting the last \( \ell \ (>1) \) successes. Hsiau and Yang [12] considered the problem with Markov-dependent trials. Recently, Ferguson [8] extended the odds theorem in several ways, where an infinite number of trials are allowed, the payoff for not selecting till the end is different from the payoff for selecting a success that is not the last, and the trials are generally dependent. Furthermore, he applied his extension to the stopping game of Sakaguchi [14].

In this paper we consider yet another extension of the result by Bruss [3]; that is, we are interested in the problem with multiple selection chances. In our first main result, we derive the optimal rule for the problem of selecting the last success with \( m \ (\in \mathcal{N}) \) selection chances and express the optimal rule as a combination of multiple odds-sums. Our extension is applied to the multi-selection versions of the problems to which the odds theorem can be applied (see, e.g. the CSP with multiple selection chances in [9] and [13]). In our second main result, we provide a formula for computing the probability of win for the problem with \( m \ (\in \mathcal{N}) \) selection chances and provide the closed-form formulae for \( m = 2 \) and 3. Furthermore, we give the lower and upper bounds for the maximum probability of win for \( m = 2 \) and derive its limit as \( \mathcal{N} \to \infty \) under some condition on \( p_i \), \( i \in \mathcal{N} \). This limit of the maximum probability of win is consistent with the known limit \( e^{-1} + e^{-3/2} \) for the CSP with two selection chances (see, e.g. [1], [2], and [9]).

This paper is organized as follows. In Section 2 we consider the optimal rule for the problem of selecting the last success with \( m \ (\in \mathcal{N}) \) selection chances. Our approach is essentially based on the technique of Ano and Ando [1], in which they studied the condition for the monotone (equivalent, one-step look-ahead) selection rule to be optimal in multiple selection problems. For more details on the monotone selection problem, we refer the reader to [6] or [7]. In Section 3 we derive some formulae for the maximum probability of win. We give the bounds for the maximum probability of win for \( m = 2 \) and derive its limit as \( \mathcal{N} \to \infty \) under some condition on \( p_i \), \( i \in \mathcal{N} \). Finally, we conclude the paper by making conjectures on the limits of the maximum probability of win for \( m \geq 3 \) and on the lower bound for \( m \geq 2 \).
2. Multiple sum-the-odds theorem

Suppose that we are given \( m \in \mathbb{N} \) selection chances in the problem described in the preceding section. Let \( V_i^{(m)}, i \in \mathcal{N} \), denote the conditional maximum probability of win provided that we observe \( X_i = 1 \) and select this success when we have at most \( m \) selection chances left. Let \( W_i^{(m)}, i \in \mathcal{N} \), denote the conditional maximum probability of win provided that we observe \( X_i = 1 \) and ignore this success when we have at most \( m \) selection chances left. Furthermore, let \( M_i^{(m)}, i \in \mathcal{N} \), denote the conditional maximum probability of win provided that we observe \( X_i = 1 \) and decide whether to select when we have at most \( m \) selection chances left. The optimality equation for each \( m \in \mathcal{N} \) is then given by

\[
M_i^{(m)} = \max\{V_i^{(m)}, W_i^{(m)}\}, \quad i \in \mathcal{N}.
\]  

(2.1)

Clearly, if \( m > N - i \) (the remaining selection chances are more than the remaining observations) and we observe \( X_i = 1 \), then the decision to select results in win with probability 1, so that \( M_i^{(m)} = V_i^{(m)} = 1 \) for \( i > N - m \). In particular, we have \( M_N^{(m)} = V_N^{(m)} = 1 \) and \( W_N^{(m)} = 0 \) for any \( m \in \mathcal{N} \).

We observe that \( V_i^{(m)} \) is represented as the sum of two conditional probabilities: the first is that no success appears in \( i + 1, \ldots, N \) provided that \( X_i = 1 \) and the second is that we finally win when starting at \( i + 1 \) with \( m - 1 \) selection chances provided that \( X_i = 1 \). Since the latter conditional probability is equal to \( W_i^{(m)} \), we have, for each \( m \in \mathcal{N} \),

\[
V_i^{(m)} = \mathbb{P}(X_{i+1} = \cdots = X_N = 0 \mid X_i = 1) + W_i^{(m-1)}, \quad i \in \mathcal{N},
\]  

(2.2)

where we set \( W_{i}^{(0)} := 0 \) for \( i \in \mathcal{N} \) and \( \prod_{j=a}^{b} q_j \cdot = 1 \) when \( b < a \) conventionally. The second equality above follows from the independence of the \( X_i \)'s. On the other hand, \( W_i^{(m)} \) is given as the conditional probability with which we finally win when we make the optimal decision at the first success after \( i \) provided that \( X_i = 1 \), so that, for each \( m \in \mathcal{N} \),

\[
W_i^{(m)} = \sum_{j=i+1}^{N} \mathbb{P}(X_{i+1} = \cdots = X_{j-1} = 0, X_j = 1 \mid X_i = 1) M_j^{(m)}
\]

\[
= \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j M_j^{(m)}, \quad i \in \mathcal{N}.
\]  

(2.3)

As a preparatory step in studying the problem with multiple selection chances, we hereby provide an alternative proof of the odds theorem (Proposition 1.1) using the notion of the monotone stopping rule in [6].

An alternative proof of Proposition 1.1. We prove only the first part of Proposition 1.1. The monotone selection region for the single selection problem is given by

\[
B^{(1)} := \{ i \in \mathcal{N} : G_i^{(1)} > 0 \},
\]

where

\[
G_i^{(1)} := V_i^{(1)} - \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j V_j^{(1)}, \quad i \in \mathcal{N}.
\]  

(2.4)
Note that $B^{(1)}$ is the region of $i \in \mathcal{N}$ such that the probability of win by selecting $X_i = 1$ is greater than that by ignoring $X_i = 1$ and then selecting the first success after $X_i$. From (2.2) we have $V^{(1)}_i = \prod_{j=i+1}^N q_j$, and, if there exists $j \in \{i+1, \ldots, N\}$ such that $q_j = 0$, then (2.4) leads to $G^{(1)}_i \leq 0$. On the other hand, if $q_j > 0$ for all $j = i+1, \ldots, N$ then (2.4) is written as

$$G^{(1)}_i = \prod_{j=i+1}^N q_j - \sum_{j=i+1}^N \left( \prod_{k=i+1}^{j-1} q_k \right) p_j \left( \prod_{k=j+1}^N q_k \right)$$

$$= \prod_{j=i+1}^N q_j \left( 1 - \sum_{j=i+1}^N r_j \right).$$

(2.5)

Therefore, if $G^{(1)}_i > 0$ for some $i \in \mathcal{N}$ then $q_j > 0$ for all $j = i+1, \ldots, N$ and (2.5) gives $\sum_{j=i+1}^N r_j < 1$. Conversely, if $\sum_{j=i+1}^N r_j < 1$ for some $i \in \mathcal{N}$ then $q_j > 0$ for all $j = i+1, \ldots, N$ and (2.5) gives $G^{(1)}_i > 0$. Namely, $G^{(1)}_i > 0$ is equivalent to $\sum_{j=i+1}^N r_j < 1$ and $B^{(1)}$ is given by

$$B^{(1)} = \left\{ i \in \mathcal{N} : \sum_{j=i+1}^N r_j < 1 \right\}.$$

Since $\sum_{j=i+1}^N r_j$ is clearly nonincreasing in $i$, $B^{(1)}$ is ‘closed’ in the sense of the monotone problem in [6]; that is, $i \in B^{(1)}$ implies that $j \in B^{(1)}$ for all $j = i, i+1, \ldots, N$. Hence, the optimal rule for the single selection problem is given by (1.1) and (1.2).

We can now state the optimal rules for the multiple selection problem.

**Theorem 2.1.** Suppose that we have at most $m (\in \mathcal{N})$ selection chances. Then, the optimal selection rule $\tau^{(m)}_s$ is given by

$$\tau^{(m)}_s = \min\{i \geq i^{(m)}_s : X_i = 1\},$$

(2.6)

$$i^{(m)}_s = \min\{i \in \mathcal{N} : H^{(m)}_i > 0\},$$

(2.7)

where $\min(\emptyset) = +\infty$ and, for each $i \in \mathcal{N}$, the $H^{(m)}_i$, $m \in \mathcal{N}$, are recursively defined by

$$H^{(1)}_i := 1 - \sum_{j=i+1}^N r_j,$$

(2.8)

$$H^{(m)}_i := H^{(1)}_i + \sum_{j=(i+1)\wedge i^{(m-1)}_s}^N r_j H^{(m-1)}_j, \quad m = 2, 3, \ldots, N,$$

(2.9)

with $a \vee b = \max\{a, b\}$ for $a, b \in \mathbb{R}$. In (2.9), if there exists a $j \in \{i+1, \ldots, N\}$ such that $p_j = 1$ (that is, $r_j = +\infty$), then we set $H^{(m)}_i := -\infty$. Furthermore, we have

$$1 = i^{(N)}_s \leq i^{(N-1)}_s \leq \cdots \leq i^{(1)}_s \leq N.$$

(2.10)

**Proof.** The monotone selection region for the problem with $m (\in \mathcal{N})$ selection chances is defined by $B^{(m)} := \{i \in \mathcal{N} : G^{(m)}_i > 0\}$, where

$$G^{(m)}_i := V^{(m)}_i - \sum_{j=i+1}^N \left( \prod_{k=i+1}^{j-1} q_k \right) p_j V^{(m)}_j, \quad i \in \mathcal{N}.$$
We have also observed that to derive (2.6) and (2.7), it suffices to show that
\( H_i^{(m)} > 0 \) is equivalent to \( H_i^{(m)} > 0 \) for each \( i \in \mathcal{N} \) and that \( i \mapsto H_i^{(m)} \) changes sign from nonpositive to positive at most once. On the other hand, to obtain (2.10), it suffices to show that \( H_i^{(m)} > H_i^{(m-1)} \) for \( i \in \mathcal{N} \) such that \( H_i^{(m-1)} > -\infty \). We verify them by induction on \( m \).

While proving Proposition 1.1, we have observed that \( G_j^{(1)} > 0 \) is equivalent to \( H_j^{(1)} > 0 \) for \( i \in \mathcal{N} \). In particular, if \( q_j = 0 \) for some \( j \in \{i+1, \ldots, N\} \) then \( G_j^{(1)} \leq 0 \), while if \( q_j > 0 \) for all \( j = i+1, \ldots, N \) then it holds that \( G_j^{(1)} = (\prod_{i=1}^{N} q_j) H_j^{(1)} \) (refer to (2.5) and (2.8)). We have also observed that \( i \mapsto H_i^{(1)} \) changes sign from nonpositive to positive at most once. The inequality \( H_i^{(2)} \geq H_i^{(1)} \) for \( i \in \mathcal{N} \) such that \( H_i^{(1)} > -\infty \) is immediately obtained from (2.9); that is,

\[
H_i^{(2)} - H_i^{(1)} = \sum_{j=0}^{N} r_j H_j^{(1)} \geq 0,
\]

where the last inequality follows from \( H_j^{(1)} > 0 \) for \( j \geq i^*_1 \).

As we apply the induction hypothesis, for \( m = 1, 2, \ldots, m \) with some fixed \( m \in \{1, 2, \ldots, N-1\} \), we now assume the following.

(i) \( G_i^{(m')} > 0 \) is equivalent to \( H_i^{(m')} > 0 \) for every \( i \in \mathcal{N} \). In particular, if \( q_j = 0 \) for some \( j \in \{i+1, \ldots, N\} \) then \( G_i^{(m')} \leq 0 \), and if \( q_j > 0 \) for all \( j = i+1, \ldots, N \) then it holds that \( G_i^{(m')} = (\prod_{j=1}^{N} q_j) H_i^{(m')} \).

(ii) \( i \mapsto H_i^{(m')} \) changes sign from nonpositive to positive at most once.

(iii) \( H_i^{(m')+1} - H_i^{(m')} \geq 0 \) for \( i \in \mathcal{N} \) such that \( H_i^{(m')} > -\infty \).

By the induction hypothesis, \( H_i^{(m')} > 0 \) and, equivalently, \( G_i^{(m')} > 0 \) for \( i \geq i^*_m \). Thus, by (i), \( q_j > 0 \) for all \( j = i^*_m + 1, \ldots, N \). Let us prove (i)–(iii) for \( m' = m + 1 \). We first examine (i). From (2.11), the monotone selection region in the case with \( m + 1 \) selection choices is given by \( B^{(m+1)} = \{i \in \mathcal{N} : G_i^{(m+1)} > 0\} \), where

\[
G_i^{(m+1)} = V_i^{(m+1)} - \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j V_j^{(m+1)}, \quad i \in \mathcal{N}. \tag{2.12}
\]

Since \( V_j^{(m+1)} = V_j^{(1)} + W_j^{(m)} \) from (2.2), substituting this into (2.12), we obtain

\[
G_i^{(m+1)} = V_i^{(1)} + W_i^{(m)} - \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j (V_j^{(1)} + W_j^{(m)}) = G_i^{(1)} + \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j (M_j^{(m)} - W_j^{(m)}), \tag{2.13}
\]

where the first term on the right-hand side is obtained from (2.4) and the second term is obtained from (2.3). By the induction hypothesis we have \( M_j^{(m)} = V_j^{(m)} \) for \( j \geq i^*_m \) and \( M_j^{(m)} = W_j^{(m)} \) for \( j < i^*_m \) in (2.1); that is,

\[
M_j^{(m)} - W_j^{(m)} = \begin{cases} V_j^{(m)} - W_j^{(m)} & \text{for } j \geq i^*_m, \\ 0 & \text{for } j < i^*_m. \end{cases}
\]
Furthermore, the induction hypothesis reads (2.3) as

\[ W_j^{(m)} = \sum_{\ell=j+1}^{N} \left( \prod_{k=j+1}^{\ell-1} q_k \right) p_{\ell} \Gamma^{(m)}_{\ell} \quad \text{for } j \geq i^{(m)}_w. \]

Therefore, from (2.11), we have

\[ M_j^{(m)} - W_j^{(m)} = G_j^{(m)} \quad \text{for } j \geq i^{(m)}_w. \]

Substituting this into (2.13), we have

\[ G_i^{(m+1)} = G_i^{(1)} + \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j G_j^{(m)}, \quad i \in \mathcal{N}. \quad (2.14) \]

Here, if \( j \in \{i + 1, \ldots, N\} \) exists such that \( q_j = 0 \), then this \( j \) is less than or equal to \( i^{(m)}_w \) since \( q_j > 0 \) for all \( j = i^{(m)}_w + 1, \ldots, N \). Namely, this occurs only for the case in which \( i < i^{(m)}_w \), where the first term on the right-hand side of (2.14) is less than or equal to 0 and the second term is equal to 0; that is, \( G_i^{(m+1)} \leq 0 \). Conversely, suppose that \( q_j > 0 \) for all \( j = i + 1, \ldots, N \) and some \( i \in \mathcal{N} \). Then, by the induction hypothesis, applying \( G_i^{(m')} = (\prod_{j=i+1}^{N} q_j) H_j^{(m')} \) for \( m' = 1 \) and \( m = m' \) to (2.14), we obtain

\[ G_i^{(m+1)} = \left( \prod_{j=i+1}^{N} q_j \right) H_i^{(1)} + \sum_{j=i+1}^{N} \left( \prod_{k=i+1}^{j-1} q_k \right) p_j \left( \prod_{\ell=j+1}^{N} q_{\ell} \right) H_j^{(m)} \]

\[ = \prod_{j=i+1}^{N} q_j \left( H_i^{(1)} + \sum_{j=i+1}^{N} r_j H_j^{(m)} \right), \]

so that (2.9) leads to

\[ G_i^{(m+1)} = \left( \prod_{j=i+1}^{N} q_j \right) H_i^{(m+1)}. \quad (2.15) \]

From the observation above, if \( G_i^{(m+1)} > 0 \) then \( q_j > 0 \) for all \( j = i + 1, \ldots, N \) and (2.15) leads to \( H_i^{(m+1)} > 0 \). Conversely, if \( H_i^{(m+1)} > 0 \) then (2.9) states that \( H_i^{(1)} > -\infty \); that is, \( q_j > 0 \) for all \( j = i + 1, \ldots, N \). Thus, (2.15) also leads to \( G_i^{(m+1)} > 0 \). Hence, we have (i) for \( m' = m + 1 \).

Next we prove (ii). By the induction hypothesis, \( H_i^{(m+1)} \geq H_i^{(m)} \) for \( i \in \mathcal{N} \) such that \( H_i^{(m)} > -\infty \) and \( H_i^{(m)} > 0 \) for \( i \geq i^{(m)}_w \); that is, \( H_i^{(m+1)} > 0 \) for \( i \geq i^{(m)}_w \). For \( i < i^{(m)}_w \), we have \( \sum_{j=(i+1)^{(m)}}^{i^{(m)}} r_j H_j^{(m)} = \sum_{j=i^{(m)}}^{N} r_j H_j^{(m)} \), which is invariant to \( i \). Thus, (2.9) states that \( H_i^{(m+1)} (= H_i^{(1)} + \text{constant}) \) is nondecreasing in \( i \) (\( < i^{(m)}_w \)). Hence, \( i \mapsto H_i^{(m+1)} \) changes sign from nonpositive to positive at most once, and (ii) holds for \( m' = m + 1 \).
Finally, to prove (iii) for \( m' = m + 1 \), we use (2.9) and take the difference between \( H_i^{(m+2)} \) and \( H_i^{(m+1)} \); that is,

\[
H_i^{(m+2)} - H_i^{(m+1)} = \sum_{j=(i+1)\lor i_k^{(m+1)}}^N r_j H_j^{(m+1)} - \sum_{j=(i+1)\lor i_k^{(m)}}^N r_j H_j^{(m)} \\
\geq \sum_{j=(i+1)\lor i_k^{(m)}}^N r_j (H_j^{(m+1)} - H_j^{(m)}) \\
\geq 0,
\]

where the first inequality follows from \( H_j^{(m+1)} > 0 \) for \( j \geq i_k^{(m+1)} \) and \( i_k^{(m+1)} \leq i_k^{(m)} \) by the induction hypothesis. The second inequality also follows from the induction hypothesis. Hence, the induction is completed and so is the proof.

Let \( h_i^{(m)} := 1 - H_i^{(m)} \) for \( i \in \mathcal{N} \). From (2.9), the \( h_i^{(m)} \) for \( m \in \mathcal{N} \) are then given by

\[
h_i^{(1)} = \sum_{j=i+1}^N r_j, \\
h_i^{(m)} = \sum_{j=i+1}^{i_k^{(m-1)}-1} r_j + \sum_{j=(i+1)\lor i_k^{(m-1)}}^N r_j h_j^{(m-1)}, \quad m = 2, 3, \ldots
\]

We can observe from the above equations that each \( h_i^{(m)} \) is expressed as a combination of multiple odds-sums. For instance, \( h_i^{(2)} \) and \( h_i^{(3)} \) are calculated as

\[
h_i^{(2)} = \sum_{j=i+1}^{i_k^{(1)}-1} r_j + \sum_{j=(i+1)\lor i_k^{(1)}}^N r_j \sum_{k=j+1}^N r_k, \quad (2.16)
\]

\[
h_i^{(3)} = \sum_{j=i+1}^{i_k^{(2)}-1} r_j + \sum_{j=(i+1)\lor i_k^{(2)}}^N r_j \left\{ \sum_{k=j+1}^{i_k^{(1)}-1} r_k + \sum_{k=(j+1)\lor i_k^{(1)}}^N \sum_{\ell=k+1}^N r_\ell \right\}.
\]

The optimal rule for the problem with \( m (\in \mathcal{N}) \) selection chances then reduces to \( t_{\ast}^{(m)} = \min\{i \in \mathcal{N} : h_i^{(m)} < 1 \} \) and \( X_1 = 1 \). Hence, we call Theorem 2.1 the ‘multiple sum-the-odds theorem’, or the ‘multiple odds theorem’ for short.

### 3. Maximum probability of win

In this section we first derive a formula for computing the maximum probability of win under the optimal rule with \( m (\in \mathcal{N}) \) selection chances and then provide closed-form formulae for \( m = 2 \) and 3. Then, we give its lower and upper bounds and the limit as \( N \to \infty \) for \( m = 2 \).

**Theorem 3.1.** For the problem with at most \( m (\in \mathcal{N}) \) selection chances, the maximum probability of win under the optimal rule, \( P^{(m)}(\text{win}) = P_N^{(m)}(p_1, \ldots, p_N) \), is given by

\[
P^{(m)}(\text{win}) = \prod_{j=i_\ast^{(m)}}^{N} q_j \prod_{j=i_\ast^{(m)}}^{N} r_j + \sum_{j=i_\ast^{(m)}}^{N} \left( \prod_{k=i_\ast^{(m)}}^{i_k^{(m)}} q_k \right) r_j W_j^{(m-1)}, \quad (3.1)
\]
where if \( p_{j(m)} = 1 \) then \( P^{(m)}(\text{win}) = \prod_{k=i_{a(m)}+1}^{N} q_k + W^{(m-1)} \) (note that \( p_j < 1 \) for all \( j = i_{a(m)} + 1, \ldots, N \)). Specifically, for \( m = 2 \) and 3,

\[
P^{(2)}(\text{win}) = \prod_{j=i_{a(2)}^{(2)}}^{N} q_j \sum_{j=i_{a(2)}^{(2)}}^{N} r_j \left( 1 + \prod_{k=j+1}^{i_{a(2)}^{(1)}-1} (1 + r_k) \sum_{k=j+1}^{N} r_k \right), \tag{3.2}
\]

\[
P^{(3)}(\text{win}) = \prod_{j=i_{a(3)}^{(3)}}^{N} q_j \sum_{j=i_{a(3)}^{(3)}}^{N} r_j \left[ 1 + \prod_{k=j+1}^{i_{a(3)}^{(2)}-1} (1 + r_k) \sum_{k=j+1}^{N} r_k \right] \times \sum_{k=(j+1)\vee i_{a(2)}^{(2)}}^{N} r_k \left( 1 + \prod_{\ell=k+1}^{i_{a(3)}^{(1)}-1} (1 + r_\ell) \sum_{\ell=k+1}^{N} r_\ell \right). \tag{3.3}
\]

**Proof.** Note that the independence of the \( X_j \)'s leads to \( P^{(m)}(\text{win}) = W^{(m)}_{i_{a(m)}^{(m)}} \) under the optimal selection rule. Thus, from (2.2) and (2.3), we obtain

\[
P^{(m)}(\text{win}) = \sum_{j=i_{a(m)}^{(m)}}^{N} \left( \prod_{k=i_{a(m)}^{(m)}}^{j-1} q_k \right) p_j M^{(m)}_j
\]

\[
= \sum_{j=i_{a(m)}^{(m)}}^{N} \left( \prod_{k=i_{a(m)}^{(m)}}^{j-1} q_k \right) p_j \left( \prod_{\ell=j+1}^{N} q_\ell + W^{(m-1)}_j \right),
\]

where the second equality follows from \( M^{(m)}_j = V^{(m)}_j \) for \( j \geq i_{a(m)}^{(m)} \). Hence, (3.1) is easily obtained.

The probabilities \( P^{(2)}(\text{win}) \) and \( P^{(3)}(\text{win}) \) are derived straightforward calculations. Since the optimal rule requires the selection of the first success after \( i_{a(1)}^{(1)} \), we have \( M^{(1)}_k = W^{(1)}_k = \prod_{\ell=k+1}^{N} q_\ell \) for \( k \geq i_{a(1)}^{(1)} \). It then follows from (2.3) that

\[
W^{(1)}_j = \sum_{k=j+1}^{N} \left( \prod_{\ell=k+1}^{N} q_\ell \right) p_k M^{(1)}_k = \prod_{\ell=j+1}^{N} q_\ell \sum_{k=j+1}^{N} r_k \quad \text{for } j \geq i_{a(1)}^{(1)} - 1.
\]

On the other hand, for \( j < i_{a(1)}^{(1)} - 1 \), we have \( W^{(1)}_j = W^{(1)}_{i_{a(1)}^{(1)}-1} = \prod_{\ell=i_{a(1)}^{(1)}-1}^{N} q_\ell \sum_{j=i_{a(1)}^{(1)}}^{N} r_j \). Therefore, for each \( j \in \mathcal{N} \),

\[
W^{(1)}_j = \prod_{\ell=(j+1)\vee i_{a(1)}^{(1)}}^{N} q_\ell \sum_{k=(j+1)\vee i_{a(1)}^{(1)}}^{N} r_k.
\]

Substituting this into (3.1) with \( m = 2 \) and using \( 1/q_k = 1 + r_k \) yields (3.2).

Using an approach similar to that used above, we obtain

\[
W^{(2)}_j = \prod_{\ell=(j+1)\vee i_{a(2)}^{(2)}}^{N} q_\ell \sum_{k=(j+1)\vee i_{a(2)}^{(2)}}^{N} r_k \left( 1 + \prod_{\ell=k+1}^{i_{a(2)}^{(1)}-1} (1 + r_\ell) \sum_{\ell=(k+1)\vee i_{a(2)}^{(1)}}^{N} r_\ell \right)
\]

Substituting this into (3.1) with \( m = 3 \) yields (3.3).
For the maximum probability of win with Odds theorem with multiple selection chances $1101 = m$ that is equal to 0 when and further proved that, if probability of win. We observe that our limit $e$ use the subscript ‘$N$’ side (RHS) above, we note that where the subscript ‘$N$’ yields $R_N^{(1)} \leq R_N^{(2)} \leq \cdots \leq R_N^{(m)} \leq \sum_{j=1}^{N} r_j$. For the single selection problem, Bruss [3] deduced that 

$$R_N^{(1)} e^{-R_N^{(1)}} < P_N^{(1)} (\text{win}) \leq R_N^{(1)} e^{-R_N^{(1)} + R_N^{(2)}}$$

and further proved that, if $R_N^{(1)} \to 1$ and $R_N^{(1,2)} \to 0$ as $N \to \infty$, then

$$P_N^{(1)} (\text{win}) \to e^{-1} \text{ as } N \to \infty.$$ 

For the double selection problem, we give the bounds and the limit as $N \to \infty$ for the maximum probability of win. We observe that our limit $e^{-1} + e^{-3/2}$ is the same as that for the CSP with two selection chances under a reasonable condition on $R_N^{(m)}$ and $R_N^{(m,2)}$ as $N \to \infty$ (see, e.g. [1], [2], and [9]).

**Theorem 3.2.** For the maximum probability of win with $m = 2$, we have

$$P_N^{(2)} (\text{win}) \geq R_N^{(1)} e^{-R_N^{(1)}} + e^{-R_N^{(2)}}, \quad (3.4)$$

$$P_N^{(2)} (\text{win}) < R_N^{(1)} e^{-R_N^{(1)} + R_N^{(2,2)}} + (1 + r_N^{(1,2)}) R_N^{(1)} + r_N^{(2,2)} e^{-R_N^{(2)} + R_N^{(2,2)}}, \quad (3.5)$$

where the inequality in (3.4) becomes strict when there is at least one $i \in \mathcal{N}$ such that $p_i > 0$. Furthermore, if $R_N^{(1)} \to 1$, $R_N^{(2)} \to 1/2$, $R_N^{(1,2)} \to 0$, and $R_N^{(2,2)} \to 0$ as $N \to \infty$, then

$$P_N^{(2)} (\text{win}) \to e^{-1} + e^{-3/2} \text{ as } N \to \infty. \quad (3.6)$$

**Proof.** We first derive the lower bound of (3.4). A simple expansion of (3.2) in Theorem 3.1 yields

$$P_N^{(2)} (\text{win}) = R_N^{(2)} \sum_{j=i_N^{(2)}}^{N} q_j + R_N^{(1)} \sum_{j=i_N^{(2)}}^{\min(i_N^{(1)}, j-1)} \left( \prod_{k=i_N^{(2)}}^{j-1} q_k \right) p_j \left( \prod_{k=i_N^{(1)}}^{N} q_k \right)$$

$$+ \sum_{j=i_N^{(2)}}^{N} q_j \sum_{j=i_N^{(2)}}^{N} r_j \sum_{k=j+1}^{N} r_k, \quad (3.7)$$

where the subscript ‘$N$’ is omitted to simplify the notation. In the second term on the right-hand side (RHS) above, we note that $\sum_{j=i_N^{(2)}}^{\min(i_N^{(1)}, j-1)} \left( \prod_{k=i_N^{(2)}}^{j-1} q_k \right) p_j = 1 - \prod_{j=i_N^{(2)}}^{\min(i_N^{(1)}, j-1)} q_j$ since it represents the probability that at least one success appears from $i_N^{(2)}$ to $i_N^{(1)} - 1$ when $i_N^{(1)} > i_N^{(2)}$ (while it is equal to 0 when $i_N^{(1)} = i_N^{(2)}$). Thus, we obtain

second term on the RHS of (3.7) = $R_N^{(1)} \left( 1 - \prod_{j=i_N^{(2)}}^{\min(i_N^{(1)}, j-1)} q_j \right) \prod_{k=i_N^{(1)}}^{N} q_k$

$$= R_N^{(1)} \left( \prod_{j=i_N^{(1)}}^{N} q_j - \prod_{j=i_N^{(2)}} q_j \right). \quad (3.8)$$
Consider the third term on the right-hand side of (3.7). Since \( h^{(2)}_i = 1 - H^{(2)}_i \geq 1 \) for \( i < i^{(2)}_s \), substituting \( i = i^{(2)}_s - 1 \) into (2.16), we have

\[
\sum_{j=1}^{i^{(1)}_s - 1} r_j + \sum_{j=i^{(1)}_s}^N r_j \sum_{k=j+1}^N r_k \geq 1,
\]

which is equivalent to

\[
\sum_{j=i^{(1)}_s}^N r_j \sum_{k=j+1}^N r_k \geq 1 + R^{(1)}_s - R^{(2)}_s.
\]

Therefore, we obtain

\[
\text{third term on the RHS of (3.7)} \geq \left( 1 + R^{(1)}_s - R^{(2)}_s \right) \prod_{j=i^{(1)}_s}^N q_j.
\]

(3.9)

Substituting (3.8) and (3.9) into (3.7) yields

\[
P^{(2)}(\text{win}) \geq R^{(1)}_s \prod_{j=i^{(1)}_s}^N q_j + \prod_{j=i^{(2)}_s}^N q_j.
\]

(3.10)

Here, noting that \( 1/q_j = 1 + r_j \) and taking the logarithm, we have, for any \( s \in \mathcal{N} \),

\[
\log \prod_{j=s}^N q_j = - \sum_{j=s}^N \log(1 + r_j) \geq - \sum_{j=s}^N r_j,
\]

where the inequality follows since \( \log(1 + x) \leq x \) for \( x \geq 0 \); the equality follows only when \( x = 0 \). Hence, we obtain \( \prod_{j=s}^N q_j \geq e^{-R} \) with \( R = \sum_{j=s}^N r_j \), where the inequality becomes strict unless \( r_s = r_{s+1} = \cdots = r_N = 0 \). Substituting this into (3.10) with \( s = i^{(1)}_s \) and \( s = i^{(2)}_s \) yields (3.4).

Next we derive the upper bound of (3.5). For this, we examine the third term on the right-hand side of (3.7). Since \( h^{(2)}_i < 1 \) for \( i \geq i^{(2)}_s \), substituting \( i = i^{(2)}_s \) into (2.16), we obtain

\[
\sum_{j=1}^{i^{(1)}_s} r_j + \sum_{j=i^{(1)}_s}^N r_j \sum_{k=j+1}^N r_k < 1,
\]

so that

\[
\sum_{j=i^{(1)}_s}^N r_j \sum_{k=j+1}^N r_k < 1 + (1 + r_{i^{(1)}_s}) R^{(1)} - (R^{(2)} - r_{i^{(1)}_s}).
\]

Therefore, we obtain

\[
\text{third term on the RHS of (3.7)} < \left( 1 + (1 + r_{i^{(1)}_s}) R^{(1)} - R^{(2)} + r_{i^{(1)}_s} \right) \prod_{j=i^{(2)}_s}^N q_j.
\]

(3.11)

Applying (3.8) and (3.11) to (3.7), we obtain

\[
P^{(2)}(\text{win}) < R^{(1)}_s \prod_{j=i^{(1)}_s}^N q_j + (1 + r_{i^{(1)}_s}) R^{(1)} + r_{i^{(1)}_s} \prod_{j=i^{(1)}_s}^N q_j.
\]

(3.12)
Here, since \(1/q_j = 1 + r_j\), using \(\log(1+x) \geq x - x^2\) for \(x \geq 0\), we obtain, for any \(s \in \mathcal{N}\),

\[
\log \prod_{j=s}^{N} q_j \leq - \sum_{j=s}^{N} r_j + \sum_{j=s}^{N} r_j^2.
\]

Hence, by assigning \(\sum_{j=s}^{N} r_j = R\) and \(\sum_{j=s}^{N} r_j^2 = R'\), we obtain \(\prod_{j=s}^{N} q_j \leq e^{-R+R'}\). Applying this in (3.12) with \(s = i(1)\) and \(s = i(2)\), we obtain (3.5).

Finally, we have \(r_{i(1)} \to 0\) and \(r_{i(2)} \to 0\) as \(N \to \infty\), since \(R_{i(1)}^{(1,2)} \to 0\) and \(R_{i(2)}^{(2,2)} \to 0\) as \(N \to \infty\), respectively. Therefore, (3.4) and (3.5) yield (3.6) as \(N \to \infty\).

As a final remark, in the multiple selection problem, we make two conjectures on the limits and lower bounds for the maximum probability of win. First, if we conjecture that \(R_{i}^{(m)}\) and \(R_{i}^{(m,2)}\), \(m = 1, 2, \ldots\), have the same limits as those for the CSP with multiple selection chances, then the limit of the maximum probability of win is also consistent with that for the CSP; that is,

\[
\lim_{N \to \infty} P_{i}^{(m)}(\text{win}) = \lim_{N \to \infty} \sum_{j=1}^{m} \frac{i(j)}{N} \quad \text{for} \quad m = 1, 2, \ldots.
\]

The case in which \(m = 1\) was solved by Bruss [3] and the case in which \(m = 2\) is solved above. For instance, for the triple selection problem, our conjecture states that, if \(R_{i}^{(1)} \to 1\), \(R_{i}^{(2)} \to \frac{3}{2}\), and \(R_{i}^{(3)} \to \frac{47}{24}\) with \(R_{i}^{(m,2)} \to 0\), \(m = 1, 2, 3\), as \(N \to \infty\), then

\[
\lim_{N \to \infty} P_{i}^{(3)}(\text{win}) = e^{-1} + e^{-3/2} + e^{-47/24}.
\]

On performing some delicate and complicated calculations, this triple selection case could be confirmed by an approach similar to that for \(P_{i}^{(2)}(\text{win})\). However, the problem of general \(m\) is more challenging.

Second, for the lower bounds for the maximum probability of win, our conjecture is stated as follows: for some reasonable condition on \(p_i\), \(i \in \mathcal{N}\),

\[
P_{i}^{(m)}(\text{win}) > \lim_{N \to \infty} \sum_{j=1}^{m} \frac{i(j)}{N} \quad \text{for} \quad m = 1, 2, \ldots.
\]

For this problem, the case in which \(m = 1\) was solved by Bruss [4]. However, the case in which \(m = 2\) is still open.
