Compelling for International Materials Leadership...

Are Recent Industry Shifts Keeping the U.S. from Fielding Its Strongest Team?

Peter R. Bridenbaugh

For the past five years, there has been a seemingly unending flow of resumes across my desk from materials scientists seeking new challenges. While this has been a wonderful opportunity for Alcoa to add talented, experienced scientists and engineers to our laboratories, it has led me to speculate whether many are giving up on the materials business. Such a retreat, if one actually exists, is particularly worrisome because we live at a time where progress on many fronts—aerospace, automotive, chemical processing, defense, biotechnology, electronics—is constrained by materials performance.

Unfortunately the available data are not clear. There is a major decline in R&D spending in the laboratories of many traditional materials companies, and to a lesser extent, some petroleum companies. But, in general, R&D spending is increasing... or, at least, remaining constant... in companies and industries where materials have clearly been identified as barriers to growth and profitability. So, what is happening?

I believe substantial shifts... in international economics, technology and governmental policies... have been occurring in our industry for several years whose impacts are now just beginning to be fully understood. For most of the decade, the primary metals/bulk chemicals industries have been very difficult businesses in which to operate profitably in the United States. This oft-repeated story... globalization, government ownership of primary capacity, commoditization and oversupply... is, by now, quite familiar. A few companies, however, are making progress by recognizing the dramatic improvement in capital productivity that can be realized from a commitment to quality and manufacturing excellence.

Second, the next generation of products have such demanding performance requirements that materials development, product design, and manufacturing processes must all be tightly integrated. These technological realities have redefined the role(s) of the semi-fabricated product producer.

And finally, the capital intensity of materials production, and the high cost of capital in this country, may be prohibiting many traditional materials companies from actively pursuing new opportunities. This is particularly acute where emerging markets are ill defined and initial volumes small. The costs of entering, or remaining, in the materials industry of the 1990s are clearly going to be high... for many, apparently, too high.

These alterations have forced players in our industry to make one of several choices... leave the commodity business, consolidate operations and abandon product development, or forward integrate toward end-product manufacture.

The results of their decisions around a materials future have clearly influenced the development and their eventual dominance of this field. It was further illustrated very recently by the selection of three airframers and two engine companies to lead the materials development program for the National Aerospace Plane. Thus, it appears certain that the government has come to perceive product manufacturers as the leaders in materials development. Again, this is not particularly surprising because of these companies' preeminence in the development of a broad range of very sophisticated systems, primarily for aerospace and defense. This perception and resulting direction has its merits, but it is also troublesome because it signals, in my opinion, an inappropriate view of the capabilities and roles of materials companies.

It is entirely possible... that we are in the midst of a subtle, but profound change in leadership within the materials industry....
of leadership even important as long as the job gets done? I clearly believe it is! Materials leadership is vital to the global success of American industry. A strong, economically viable and technically astute materials industry represents this nation's best chance to overcome today's complex product and process challenges. And any factors that effectively limit our full participation in this international industrial contest must be viewed with this realization in mind.

Today, we have the ability to measure properties and to study microstructures at levels unheard of 10 years ago. Numerically intense computing has enabled the modeling and display of phenomena we could only imagine when this decade began. Together, these scientific and computing advancements have forever changed the nature of materials R&D by giving us the capability to understand materials behavior as never before. But who is best qualified to fully leverage this knowledge...the materials company or the product manufacturer?

There is, of course, no single answer to this question. Perhaps our experience at Alcoa Laboratories can provide some insight. We have found the application of these "tools" is considerably enhanced when incorporated with our knowledge of materials behavior, gained from a century of research and development. This applies even as we have moved into new materials systems. However, in order to reap the rewards of our materials developments, we have found it necessary to pursue product manufacture. We have expanded our design capabilities, developed new manufacturing processes and integrated both with our materials development expertise. This integration of materials science, design, and manufacturing has allowed us to break new ground in materials performance.

The Department of Defense policies linking independent R&D reimbursement to government sales also need to be re-examined. Traditional materials companies are at a competitive disadvantage because they have historically not been major government contractors and therefore are placed in the position of using their own earnings, not government-reimbursed funds, to pursue proprietary materials development. This often keeps those best qualified to develop new materials and processes from making their maximum contribution.

Finally, the "authorization and consent clause" in our patent law, which has been perceived by many in recent years as a carte blanche for patent infringement, must be revised to clarify and protect the rights of patent owners.

We must challenge any factor, other than the marketplace itself, that keeps key players from bringing all their resources to the table in what is a high-stakes, international competition for materials and manufacturing pre-eminence. The outcome of this contest will influence nothing less than the standard of living of the United States.

Peter R. Bridenbaugh is vice president of research and development, Aluminum Company of America, Pittsburgh, Pennsylvania.
