

depression. Clinical judgement: manic episode. Bipolar disorder Type I

Conclusions: After dismissing somatic causes, the symptomatic treatment of a manic episode in older patients is on the same lines as the treatment for mania in young adults. 8-10% of psychiatric inpatients over age 55-60 years are diagnosed with bipolar disorder. Since there is an increase in the number of individuals living longer, an expected increase in the number of older adults who will be diagnosed with bipolar disorder. Older adults with bipolar disorder will increase in absolute numbers as well as the proportion of the general populations.

Introduction: Bipolar Disorders (BD) are regarded as a multidimensional disease involving both psychological and physical determinants. Although mood dimension and thymic instability are considered as the « core » aspect of bipolar disorders, it is crucial to note that somatic problems frequently occur in BD, deeply worsening the prognosis.

Objectives: Here we describe a case of a twenty-year history of psychiatric impairment, diagnosed later with cardiac malformation.

Methods: Female patient H.G has been admitted for the first time to psychiatric department 'A' of Razi Hospital, treated for type 1 bipolar disorder since 2004 with poor therapeutic compliance. We reviewed the clinical and paraclinical data.

Results: The patient was hospitalized for a severe manic episode with psychotic features, without cardiac personal history. The patient was asymptomatic and physical examination showed no abnormalities. Following a routine electrocardiogram, an acute coronary syndrome was discovered (inverted T waves seen in V1 to V6). Cardiac troponins were not elevated. According to cardiology recommendations, ischemic heart disease could not be ruled out and extensive cardiovascular investigations were needed. Antipsychotics and mood stabilizers were contraindicated. Therefore, the manic episode could only be managed using benzodiazepines. Given contradictions between clinical, electrocardiographic and imaging findings, coronary angiography was necessary. Results showed no significant stenosis of coronary arteries and a myocardial bridging of the left anterior descending artery and we were able to put her on antipsychotics and mood stabilizer, almost two months after her admission.

Conclusions: This case underlines the significant impact of somatic comorbidities in therapeutic management of bipolar disorders. Cardiovascular diseases in particular cause a delay in treatment initiation and an increase in patient length of hospital stay.

Introduction: Bipolar disorder (BD) is frequently underdiagnosed and due to poor screening, the average time between onset of symptoms and diagnosis is more than 7-years (Mantere et al., 2004). Improper diagnosis has serious consequences in intervention (Ghaemi et al., 2001), and previous assessment instruments are now considered insufficient to detect intervention changes, and to provide a more functional and integrated view of BD.

Objectives: Our study aims to develop a new DSM-5 based Clinical Interview for Bipolar Disorder (CIBD), providing criteria to diagnose BD, but also the individual's perceptions dealing with BD symptoms. This interview follows the same structure of CIPD (Martins et al., 2015), which has shown acceptability by the participants and experts.

Methods: CIBD was developed by a multidisciplinary team considering the DSM-5 criteria for Bipolar Disorders. There was a thorough research regarding assessment and evaluation of BD, and several suggestions from an international task force of specialist working with BD patients were considered, when writing the questions for the interview. A detailed description of CIBD development is presented. The authors of the interview have extended experience in the management and assessment of BD patients, and CIBD is now being assessed by a wider non-related panel, regarding pertinence and clarity.

Results: Preliminary assessment and qualitative feedback from participants that were interviewed is shown, with an overall positive feedback.

Conclusions: CIBD assesses both the diagnosis/presence of mood episodes (hypo/mania, and depressive) and symptoms' psychosocial correlates. CIBD detects subtle changes caused by intervention adding a much needed recovery focused perspective.

That's not my family: The undercover bipolar patient

M.F. Tascon Guerra

Psychiatry, Hospital Ntra Sra del Prado, Talavera de la Reina, Toledo, Spain

doi: 10.1192/j.eurpsy.2021.1647

Introduction: Bipolar disorder is a serious psychiatric condition based on depressive, manic, and mixed phases. Bipolar disorder has been usually divided into type I (manic phases and depressive

phases) and type II (hypomanic and depressive phases). Furthermore, subsequent classifications have been developed based on subtypes complexity.

Objectives: A case of a 52-year-old man is presented. The patient had suffered depressive symptoms and self-destructive ideation. He had sold his house to pay for drugs and prostitution, even though he was in quarantine for COVID-19. The patient had a history of depressive episodes with milder manic episodes which had been treated with antidepressants.

Methods: Analytical and imaging tests were performed without findings. Mood stabilizing treatment was started based on lithium salts. He became perplexed and suspicious of the medication. Auditory hallucinations appeared congruent with the mood and he began to think that his relatives were dead; the patient started to communicate via telephone with actors. A treatment based on olanzapine 30mg/d was started.

Results: The clinic was resolved with antipsychotic treatment. The diagnosis of Bipolar Disorder has been made in youth; however, some patients symptoms could be camouflaged and allow a functional life. Depressive episodes could present with psychotic symptoms and predispose more to suicide attempts than manic phases.

Conclusions: The early-stage diagnosis should play a key role on bipolar disorder control. More public and clinic efforts are needed to prevent non-easily distinguishable cases which could derived on serious social and health problems.

doi: 10.1192/j.eurpsy.2021.1648

Introduction: Treating pregnant women with bipolar disorder is among the most challenging clinical endeavors. Patients and clinicians are faced with difficult choices at every turn, and no approach is without risk. Many primary mood stabilizers have been associated with risk of congenital malformations. In the last 15 years, there has been an increase of antepartum use of atypical antipsychotic drugs, many of which could be viable alternatives to mood stabilizers. Electroconvulsive therapy has been recommended as a safe and efficacious treatment of bipolar depressive and manic episodes in pregnant women.

Objectives: This case presents a 24-year-old woman, with COVID-19 infection, that underwent an acute manic episode at her 20-weeks-pregnancy. The goal was to stabilize the patient by the use of electroconvulsive therapy.

Methods: The patient was admitted in isolation in the psychiatric ward. Treatment was started with olanzapine 20mg/d and lorazepam 4mg/d. The patient maintained psychotic agitation that required higher dosage, while on the second week of isolation the

PCR test was negative. After six weeks of treatment severe manic symptoms continued and electroconvulsive therapy was started.

Results: She received 10 electroconvulsive therapy sessions. The patient showed a substantial clinical improvement after the seventh administration. She gave birth at 37 weeks, with no complications during labor (Apgar 9/10).

Conclusions: Electroconvulsive therapy has been shown as a suitable option for patients with severe psychiatric disorders in the pregnancy period, either medication resistant illness and psychotic agitation.

doi: 10.1192/j.eurpsy.2021.1649

Introduction: Bipolar disorder (BD) is a common and disabling condition. Gender differences are potentially important and can manifest in many ways.

Objectives: To determine the socio-demographic characteristics of women with BD, followed at the department of psychiatry of Gabes (southern of Tunisia).

Methods: A retrospective descriptive and analytical study was undertaken including all the patients having consulted for the first time in the department of psychiatry of Gabes, from January 1st, 2010 to December 31, 2016, for whom the diagnosis of a bipolar disorder was established according to the DSM-IV criteria. Socio-demographic and clinical data were assessed. Patients were divided into two groups according to gender. The collected data was compared between the two groups. The statistical analysis was executed on the software SPSS (20th edition).

Results: We included 193 patients with BD (women = 103). The mean age of the women studied was 39.9 years. Women with BD had the following characteristics: married (55.3%), unemployed (65.1%), having an urban origin (75.7%), attending the primary or secondary school level (76.7%) and with an middle socioeconomic level (62.1%). Among the women studied, 9 (8.7%) were smokers, 2 (1.9%) consumed alcohol, and one (0.9%) used cannabis. Regarding the socio-demographic differences by gender, bipolar women were significantly less professionally active ($p < 0.03$), less educated ($p = 0.009$), more frequently married, widowed or divorced ($p < 0.03$) and having dependent children ($p = 0.008$).

Conclusions: Our study made it possible to note the socio-demographic particularities of the woman followed for BD. A better knowledge of these particularities is the best guarantee of adequate care.
