Learning Objectives: The consistent performed and long-term follow-up after cholesteatoma surgery is essential for the evaluation and a prerequisite for a comparison of the surgical results.

Introduction: The aim of the study was to present and compare data from two separate studies of a 6-years follow-up after cholesteatoma surgery in adults and children.

Material and methods: 301 adult- (330 ears) and 57 paediatric patients were operated for cholesteatoma. In all cases an identical one-stage canal-wall down-technique with reconstruction of the middle ear and mastoid obliteration using autologous bone was used. In the adult group 47% had previous surgery, in the paediatric group 7%.

After surgery a standardized protocol for documentation of the intra- and postoperative findings and surgical steps including a sketch and the preoperative audiometric data -pure tone average (PTA) for air- and bone conduction threshold levels (0.5–3kHz) - were registered in the data based follow-up-program. All patients were examined annually after surgery and the surgical and the audiometric data fed into the program 1, 3 and 6 years after surgery.

Results: In the adult group residual disease was found in 3%, in the paediatric group in 5%. The recurrence rate was 10% and 12%. Chain revisions were performed in 19% and 14%. The rate of the postoperative water resistance was 5% and 7%, the postoperative infection rate 3% and 0%.

Long lasting improvement and/or preservation of hearing were obtained in both groups. The pre-and postoperative air conduction hearing levels were 45.8 dB and 35.8 dB in the adult group, in the paediatric group 33 dB and 25.5 dB.

Conclusions: Independent of preoperative middle ear condition, cholesteatoma extent and localization, the used surgical technique provided a long-term improvement of hearing with a low incidence of residual and recurrent disease. No differences in outcome between adult and children were found.

Learning Objectives:

Introduction: Musculoskeletal pain is a common occupational hazard experienced by surgeons. Within the ENT community, Otologists have been noted to experience the most neck and back pain, possibly related to prolonged microscopic work.

Aims:

1. To investigate the effects of sustained microscopic work on the neck and back and its correlation to surgical experience
2. To assess the benefits of a prototype ergonomic chair during prolonged microscopic work

Methods: A crossover study was performed on 10 male ENT clinicians using a standard operating chair and a prototype ergonomic support chair. We used a subjective measure of time to fatigue and pain for the neck and back as well as objective readings from a surface electromyogram (sEMG).

Results: Surgeon experience (years) was correlated with the time (sec) to fatigue at the neck (R = 0.91, p < 0.001) and back (R = 0.76, p = 0.01) as well as time to pain at the neck (R = 0.74, p = 0.01) and back (R = 0.78, p < 0.01) when the standard chair was used. Group mean time to onset of neck fatigue was 348s, neck pain was 846s, back fatigue was around 520s and back pain was 821s. The prototype ergonomic support chair significantly delayed the sensation of neck fatigue (+672 ± 520s, p < 0.01) and neck pain (+427 ± 467s, p = 0.017) and also eliminated the
