cavity had a recurrent infection in the mastoid cavity, the
muitus opened and discharge persisted. All other operated
patients ears stopped discharging therefore the success
rate in this series is 95%. There were no major complica-
tions after surgeries. All patients who had a bone anchored
hearing device or a cochlear implant presented benefit from
their devices.

Conclusion: Patients with weeping cavities are debilitated
due to water precautions, vestibular effect, the reduced
hearing and the discharge that can be extremely disturbing.
A debilitating weeping cavity which does not respond to
medical treatment is a surgical disease. In such patients
STP with hearing rehabilitation should be suggested.

Outcomes following trans-mastoid
occlusion surgery for superior
semicircular canal dehiscence

Presenting Author: Suzanne Jervis

Suzanne Jervis¹, Maarten de Wolf², Jeyanthi Kulasegarah¹, Karen Lindley¹, Richard Irving¹
¹University Hospitals Birmingham NHS Trust, ²Amsterdam

Learning Objectives:

Introduction: Semicircular canal dehiscence syndrome (SCDS)
is caused by a bony defect of the superior semicircular canal,
resulting in autophony, bone conduction of bodily sounds and
pseudo conductive hearing loss. Vestibular manifestations
include sound or pressure evoked vertigo. Oclucling the dehis-
cent canal was originally described via the middle cranial fossa
approach however, an alternative transmastoid approach has
been used to avoid the morbidity associated with the former.
The aim of this project was to determine clinical and audiologic-
al outcomes for those undergoing the transmastoid approach.

Methods: All patients suggestive of SCDS underwent CT
scanning, cVEMP testing. All those with positive findings
for both (dehiscent superior canal and cVEMP thresholds
>35%) underwent surgery. Audiometric data were obtained
and patients were sent questionnaires retrospectively regard-
ing their symptoms.

Results: Twenty patients, with 22 affected ears underwent sur-
gical occlusion. The commonest reported symptoms pre-oper-
tively were hearing internal sounds, tinnitus, and fullness
sensation (95%, 95%, and 82% respectively.) The symptoms
most likely to show partial or complete improvement post
operatively were hearing internal sounds, vertigo to loud
sounds and imbalance (91%, 88% and 87% respectively.)
Symptom deterioration occurred in two ears with respect to
fullness. 9 patients developed new symptoms post operatively
(of ‘mild nature’), the most common being imbalance (3) and
fullness (2). Overall, 15 ears (68%) showed partial or complete
symptom improvement, 6 showed no change and 1 was worse.
The mean Dizziness Handicap Inventory Scores improved
from 43 pre-op to 24 post op (p = 0.001). The mean air conduction
(Fletcher’s index) improved from 13.2 dB to 11.1 dB.

Conclusion: The transmastoid approach to the superior canal
appears to be well tolerated and is associated with low risk to
hearing. Symptom improvement is seen in two thirds, but
temporary imbalance post op is common.

The Hong Kong Vascularized Temporalis
Fascia Flap and its role in Cholesteatoma
Surgery revisited

Presenting Author: Andrew van Hasselt

Andrew van Hasselt¹, Michael Tong², Kwok Chung Liu²
¹The Chinese University of Hong Kong, ²Chinese University of Hong Kong

Learning Objectives: When reconstructing large mastoid
cavities, the surgeon’s repertoire should include a technique
that uses a vascularized lining to optimize patient outcomes.

Introduction: Complications following open cholesteatoma
surgery arise when mastoid cavities fail to epithelialize. The
Hong Kong flap is a fertile substrate of vascularized
temporalis fascia lining that facilitates rapid epithelial
lining. We have studied the long term outcome of this tech-
nique and reviewed its role in cholesteatoma surgery.

Methods: We analyzed data obtained from records of patients
who have had cholesteatoma surgery in the Prince of Wales group of hospitals through the period
from 1987 to 2015. The outcome measures included rele-
vant clinical parameters such as time to achieve a dry ear,
requirement for a second look procedure and the primary
surgeon’s level of experience.

Results: The Hong Kong flap reconstruction was not utilized
in all of cholesteatoma operations over this period. In patients
reconstructed with the Hong Kong flap, the median time to
dry ear was 2 months. 20% needed a second look or more
and 8% were found to have recurrent or residual choleste-
toma. Surgeons with varying levels of surgical experience
successfully performed the procedure.

Conclusions: The Hong Kong vascularized temporalis fascia
flap is a technique within the capability of average otologists.
The post-operative course is categorized by rapid healing and
long term healthy, trouble free cavities. The requirement for
second look procedures is significantly reduced.

Otology Questionnaire Amsterdam
(OQUA): preliminary results on
the development of a general otologic
questionnaire
ABSTRACTS

1VU University Medical Center Amsterdam, 2Isala hospital, 3Amstelland hospital, 4Erasmus University Medical Center

Learning Objectives: - Patient Related Outcome Measures are increasingly important in the evaluation of ear complaints. - Most patients with ear complaints suffer from multiple ear complaints or changing complaints after treatment. - The development and future implementation of a general otologic questionnaire will help to improve otologic care in all patients with ear complaints. - Multiple steps are needed to develop and validate a well-designed questionnaire.

Introduction: Most patients visiting an ENT-doctor because of an ear complaint suffer from multiple ear complaints. Patient Reported Outcome Measures (PROMs) are useful in the evaluation of these complaints. However, there is no well-validated, Dutch PROM available that contains items about all types of ear complaints.

Objectives: Development and validation of a questionnaire (OQUA), applicable to all adult patients visiting an ENT-doctor because of an ear complaint. The OQUA needs to cover all common ear complaints and all three parts of the questionnaire (severity, impact and change over time) must be able to be evaluated separately.

Methods: Patients over the age of sixteen who presented themselves to an ENT-doctor with an ear complaint were recruited for a series of studies. First, qualitative research was performed by field-testing (N = 32, N = 39) was performed. Finally, quantitative research was performed by field-testing (N = 352). Item reduction took place based on factor and reliability analyses.

Results: In the qualitative phase, eight domains of ear complaints were identified: earache, hearing loss, otorhhea, dizziness, itch, tinnitus, pressure in ear and loss of taste. In the quantitative phase, ten out of fifty items were removed based on factor analysis, seventeen items were removed based on reliability analysis. Based on factor analysis, nine factors emerged. The current version of the OQUA comprises twenty-three items, covers all eight domains of ear complaints and contains eleven items about complaints that often occur in patients with cholesteatoma.

Conclusions: Many patients with an ear complaint report several ear complaints. The current version of the OQUA questionnaire serves as a good basis for the development of the final, validated version of this questionnaire.

Otoendoscopy assisted Combined Approach Tympanoplasty: Can it replace posterior tympanotomy

Presenting Author: Ahmed Allam

Ahmed Allam1, Panos Dimitriadis2, Jadip Ray2

1Otology/Neurotology Fellow in Sheffield Teaching Hospital, 2Regional Department of Neurotology, Sheffield Teaching Hospital, UK

Learning Objectives:

Background: The aim of combined approach tympanoplasty is to middle ear and mastoid eradicate the disease and obtain dry ear whilst preserving the structure and function of the middle ear as far as possible. Facial recess and sinus tympani are anatomic sites that are difficult to assess with a microscope. Hence a posterior tympanotomy is used by most surgeons as a standard step for clearance of these areas. Otoendoscopy also allows excellent visualization of these areas and reduces surgical steps and time.

Aim of the study: To compare between the recurrence rate of secondary cholesteatoma following CAT surgery using either posterior tympanotomy or otoendoscopy.

Study design: Retrospective case review over a period of 10 years at a single centre.

Setting: Regional Department of Neurotology, Sheffield Teaching Hospital, UK.

Inclusive criteria: We included every CAT that was performed in adults (>16 yr), by a single surgeon (senior author), for acquired cholesteatoma between 2006 and 2015, with a 12-month disease-free interval.

Results: A total number of 152 CAT (stage 1) procedures done between 2006 and 2015 by a single surgeon were included. Of these 25 (16%) cases (ears) showed evidence recurrent cholesteatoma as demonstrated by imaging (T2 weighted non EPI MRI) needing a second look procedure. 17 of them could be retained as a closed cavity (CAT stage 2) whilst 8 cases were converted into an open mastoid cavity (Modified Radical Mastoidectomy). Analysed in their own subgroups the recurrence rate in those with a posterior tympanotomy was 26% (18/70 cases) whilst it was 8% (7/82 cases) in those where the otoendoscope was used.

Conclusion: Otoendoscopy provides a simple and reliable approach for managing cholesteatoma in facial recess area in combined approach tympanoplasty. When used carefully and meticulously it can be used in place of a posterior tympanotomy approach with comparable results.
