DUALITY WITH GENERALIZED CONVEXITY

R. R. EGUDO\(^1\) AND B. MOND\(^2\)

(Received 15 August 1984; revised 25 March 1985)

Abstract

Recently, Hanson and Mond formulated a type of generalized convexity and used it to establish duality between the nonlinear programming problem and the Wolfe dual. Elsewhere, Mond and Weir gave an alternate dual, different from the Wolfe dual, that allowed the weakening of the convexity requirements. Here we establish duality between the nonlinear programming problem and the Mond-Weir dual using Hanson-Mond generalized convexity conditions.

1. Introduction and preliminaries

In Hanson and Mond [2], generalized convexity was defined by use of sublinear functionals which satisfy certain convexity type conditions. Wolfe duality was shown to hold under the assumption that a sublinear functional exists such that the Lagrangian satisfies generalized convexity conditions. In [7] Mond and Weir gave a dual for (P), different from the Wolfe dual, where the convexity requirements for duality are considerably weakened. Here we present and prove duality of the Mond-Weir type under the Hanson and Mond [2] generalized convexity conditions. We also give a strict duality theorem which generalizes the strict duality given in Gulati and Craven [1], Mond and Egudo [6], and Weir [8].

**Definition 1.** A functional $F$ is sublinear over a space $S$ if

(A) \[ F(x + y) \leq F(x) + F(y) \quad \forall x, y \in S \]

(B) \[ F(ax) = aF(x) \quad \text{for } a \in \mathbb{R}, a > 0, x \in S. \]

From (B) it follows that $F(0) = 0$.

**Definition 2.** A differentiable function $\phi(x)$ defined on some set $X \subset \mathbb{R}^n$ is said to be $F$-convex if

\[ \phi(x_1) - \phi(x_2) \geq F_{x_1,x_2}[\nabla \phi(x_2)] \quad (1) \]

where $\nabla \phi(x)$ is the gradient of $\phi$ and $x_1, x_2 \in X$ and for some arbitrary given sublinear functional $F$.

**Definition 3.** A differentiable function $\phi(x)$ defined on some set $X \subset \mathbb{R}^n$ is said to be $F$-quasiconvex if

\[ \phi(x_1) \leq \phi(x_2) \Rightarrow F_{x_1,x_2}[\nabla \phi(x_2)] \leq 0 \quad (2) \]

where $\nabla \phi(x)$ is the gradient of $\phi$ and $x_1, x_2 \in X$ and for some arbitrary given sublinear functional $F$.

**Definition 4.** A differentiable function $\phi(x)$ defined on a subset $X$ of $\mathbb{R}^n$ is said to be $F$-pseudoconvex if

\[ F_{x_1,x_2}[\nabla \phi(x_2)] \geq 0 \Rightarrow \phi(x_1) \geq \phi(x_2) \quad (3) \]

where $\nabla \phi(x)$ is the gradient of $\phi$ and $x_1, x_2 \in X$ and for some arbitrary given sublinear functional $F$.

**Definition 5.** A differentiable function $\phi(x)$ defined on $X \subset \mathbb{R}^n$ is said to be strictly $F$-pseudo-convex if for $x_1, x_2 \in X, x_1 \neq x_2$,

\[ F_{x_1,x_2}[\nabla \phi(x_2)] > 0 \Rightarrow \phi(x_1) < \phi(x_2) \quad (4) \]

where $\nabla \phi(x)$ is the gradient of $\phi$ and $x_1, x_2 \in X$ and for some arbitrary given sublinear functional $F$.

As pointed out in Mond [5], $F$-convex functions can be regarded as a generalization of convex functions. Similarly $F$-pseudoconvex functions and $F$-quasi-convex functions can be regarded as generalizations of pseudoconvex and quasiconvex functions respectively.

Now consider the following pair of nonlinear programming problems:

(P) Minimize $f(x)$
subject to $g(x) \leq 0$;

(DW) Maximize $f(u) + y^T g(u)$
subject to $\nabla f(u) + \nabla y^T g(u) = 0$,
$y \geq 0$;

where $f: \mathbb{R}^n \to \mathbb{R}$, $g: \mathbb{R}^n \to \mathbb{R}^m$ are differentiable functions.

Let $S$ denote the feasible region of (P) i.e., $S = \{x : g(x) \leq 0\}$.

Hanson and Mond [2] have established the following results.

**THEOREM 1 (Weak duality).** If for all feasible $x$ in $(P)$ and feasible $(u, y)$ in $(DW)$ there exists a sublinear functional $F$ such that the Lagrangian $f + y'g$ is $F$-pseudo-convex, then $\text{Min}(P) \geq \text{Max}(DW)$.

**THEOREM 2 (Strong duality).** If $x^0$ is a local or global optimal for $(P)$ and a constraint qualification is satisfied at $x^0$, then there exists a $y^0 \in \mathbb{R}^m$ such that $(x^0, y^0)$ is feasible in $(DW)$ and the corresponding values of $(P)$ and $(DW)$ are equal. If, also, for all feasible $x$ in $(P)$ and feasible $(u, y)$ in $(DW)$, there exists a sublinear functional $F$ such that $f + y'g$ is $F$-pseudoconvex, then $x^0$ and $(x^0, y^0)$ are global optima for $(P)$ and $(DW)$ respectively.

2. Mond-Weir type duality

We establish duality between $(P)$ and the following Mond-Weir dual (DMW).

$$(DMW) \quad \text{Maximize } f(u)$$

subject to $\nabla f(u) + \nabla y'g(u) = 0$, \hspace{1cm} (8)

$y'g(u) \geq 0$, \hspace{1cm} (9)

$y \geq 0$. \hspace{1cm} (10)

**THEOREM 3 (Weakly duality).** If for all feasible $x$ in $(P)$ and feasible $(u, y)$ in $(DMW)$ there exists a sublinear functional $F$ such that, for feasible $(x, u, y)$ $f$ is $F$-pseudoconvex and $y'g$ is $F$-quasiconvex, then Minimum $(P) \geq$ Maximum $(DMW)$.

**Proof.** Since $x$ is feasible for $(P)$ and $(u, y)$ is feasible for $(DMW)$, we have from (5), (9) and (10) that

$$y'g(x) - y'g(u) \leq 0$$

and, since $y'g$ is $F$-quasiconvex (11) implies

$$F_{x,u}[\nabla y'g(u)] \leq 0.$$ \hspace{1cm} (12)

From sublinearity of $F$ we have

$$F_{x,u}[\nabla f(u) + \nabla y'g(u)] \leq F_{x,u}[\nabla f(u)] + F_{x,u}[\nabla y'g(u)].$$ \hspace{1cm} (13)

Also from (8) and sublinearity of $F$ we obtain

$$F_{x,u}[\nabla f(u) + \nabla y'g(u)] = 0.$$
Now this and (13) yield
\[
F_{x,u}[\nabla f(u)] \geq -F_{x,u}[\nabla y'g(u)]
\]
\[
\geq 0,
\]
where (14) follows from (12). Now (14) and \(F\)-pseudoconvexity of \(f\) yields \(f(x) \geq f(u)\).

**Theorem 4 (Strong duality).** Let \(x^0\) solve (P) and assume a constraint qualification is satisfied at \(x^0\). Suppose also that a sublinear functional \(F\) exists such that \(f\) is \(F\)-pseudoconvex and \(y'g\) is \(F\)-quasiconvex for all feasible \(x\) in (P) and \((u, y)\) in (DMW). Then there exists a \(y^0\) such that \((x^0, y^0)\) solves (DMW) and Minimum \((P) = Maximum (DMW)\).

**Proof.** Since \(x^0\) solves (P) and a constraint qualification is satisfied at \(x^0\), from Kuhn-Tucker conditions there exists a \(y^0 \in \mathbb{R}^m\) such that \((x^0, y^0)\) is feasible for (DMW). Clearly the objective functions of (P) and (DMW) are equal, so the value of (P) equals the value of (DMW) at \(x^0\). Optimality now follows from weak duality.

We now give an example where Theorems 1 and 2 fail to apply while Theorems 3 and 4 hold.

**Example 1.**

Minimize \(f(x) = x_1^3 - x_2^3 + x_3^3 + x_3\)
subject to \(g_1(x) = x_1^2 - 2x_1^3 + x_2^2 + 2x_2^3 + 1 \leq 0,\)
\(g_2(x) = -x_2^2 + 1 \leq 0,\)
\(g_3(x) = -x_3 + 1 \leq 0.\)

An optimal solution is attained at \(x^0 = (0, -1, 1)\). Now \(x^0 = (0, -1, 1)\) is feasible for (P) and \((u^0, y^0) = (0, 0, 1, 1, 1, 4)\) is feasible for the Wolfe dual, that is

Maximize \(u_1^3 - u_2^3 + u_3^3 + u_3 + y_1(u_1^2 - 2u_1^3 + u_2^3 + 2u_2^3 + 1)\)
\(\quad + y_2(1 - u_2^2) + y_3(1 - u_3)\)
subject to
\[
\begin{bmatrix}
3u_1^2 \\
-3u_2^2 \\
3u_3^2 + 1
\end{bmatrix} = -y_1
\begin{bmatrix}
2u_1 - 6u_1^2 \\
2u_2 + 6u_2^2 \\
0
\end{bmatrix} - y_2
\begin{bmatrix}
0 \\
-2u_2 \\
0
\end{bmatrix} - y_3
\begin{bmatrix}
0 \\
0 \\
-1
\end{bmatrix}.
\]

Now \(f(0, -1, 1) = 3\), but \(f(u^0) + y^0'g(u^0) = 4\), where \(u^0 = (0, 0, 1), y^0 = (1, 1, 4)\). Hence weak duality does not hold. Also by considering the third constraint, that is \(y_3 = 3u_3^2 + 1\), we find that the objective function tends to infinity as \(u_3\) tends to minus infinity for any feasible \(u_1, u_2, y_1\) and \(y_2\). Hence strong duality does not hold.
Examining \( f(x) \equiv x_1^4 - x_2^3 + x_3^3 + x_4 \), we find that \( f(x) \) is not pseudo-convex over the feasible region. Hence Mond-Weir results [7] do not apply between Example 1 and its Mond-Weir dual

Maximize

\[
\begin{bmatrix}
3u_1^2 \\
-3u_2^2 \\
3u_3^2 + 1
\end{bmatrix}
= -y_1
\begin{bmatrix}
2u_1 - 6u_1 \\
2u_2 + 6u_2 \\
0
\end{bmatrix}
- y_2
\begin{bmatrix}
0 \\
0 \\
-1
\end{bmatrix},
\]

\( y_1(u_1^2 - 2u_1^3 + u_2^2 + 2u_3^3 + 1) \geq 0, \)

\( y_2(1 - u_2^2) \geq 0, \)

\( y_3(1 - u_3) \geq 0, \)

\( y_1 \geq 0, \quad y_2 \geq 0, \quad y_3 \geq 0. \)

However, if we define

\[
F_{x,u}[z] = \left( \sum_{i=1}^{3} |z_i| + a^t z \right) (f(x) - f(u) + g_1(x) + g_2(x)),
\]

where \( a^t = (1, -1, 1) \) and \( x \) is feasible in (P) and \( u \) is feasible in (DMW), then

\[
F_{x,u}[\nabla f(u)] = (6(u_1^2 + u_2^2 + u_3^2) + 2)(f(x) - f(u) + g_1(x) + g_2(x)) \leq (6(u_1^2 + u_2^2 + u_3^2) + 2)(f(x) - f(u)),
\]

since \( g_1(x) \) and \( g_2(x) \) are non-positive for feasible \( x \) in (P). Hence

\[
f(x) - f(u) \geq \frac{1}{6(u_1^2 + u_2^2 + u_3^2) + 2} F_{x,u}[\nabla f(u)].
\]

So \( F_{x,u}[\nabla f(u)] \geq 0 \Rightarrow f(x) \geq f(u). \) Therefore, \( f \) is \( F \)-pseudoconvex for all feasible \( x \) and \( u \). Also, since \( x \) is feasible for (P) and \( (u, y) \) is feasible for (DMW), we have

\[
y^t g(x) - y^t g(u) \leq 0
\]

and

\[
F_{x,u}[\nabla y^t g(u)] = F_{x,u}[-\nabla f(u)] = F_{x,u}
\begin{bmatrix}
-3u_1^2 \\
3u_2^2 \\
-3u_3^2 - 1
\end{bmatrix}
= (3u_1^2 + 3u_2^2 + 3u_3^2 + 1 - 3u_1^2 - 3u_2^2 - 3u_3^2 - 1)
\cdot \left( f(x) - f(u) + g_1(x) + g_2(x) \right).
\]

\[
= 0,
\]
Hence \( y'g \) is \( F \)-quasiconvex for all feasible \((x, u, y)\). So Theorem 3 is applicable to this pair of nonlinear programs. Now \( x^0 = (0, -1, 1) \) solves the primal program and for \((x^0, y^0) = (0, -1, 1, \frac{1}{2}, 4)\), \((x^0, y^0)\) is feasible and hence optimal in (DMW) with equality of objective functions.

We now give general results which subsume the different Mond-Weir type duals for the primal problem (PE).

\[ \text{(P)} \quad \text{Minimize} \quad f(x), \]
\[ \text{subject to} \quad g(x) \leq 0, \quad h(x) = 0. \tag{15} \tag{16} \]

The general Mond-Weir dual to (PE) is (DEG) [7].

\[ \text{(DEG)} \quad \text{Maximize} \quad f(u) + y^T_l g_{l_a}(u) + z^T_j h_{j_a}(u) \]
\[ \text{subject to} \quad \nabla y^T g(u) + \nabla z^T h(u) + \nabla f(u) = 0, \]
\[ y^T_l g_{l_a}(u) + z^T_j h_{j_a}(u) \geq 0, \quad \alpha = 1, 2, \ldots, r, \tag{17} \tag{18} \]
\[ y \geq 0, \quad \tag{19} \]

where \( f: \mathbb{R}^n \to \mathbb{R}, \ g: \mathbb{R}^n \to \mathbb{R}^m, \ h: \mathbb{R}^n \to \mathbb{R}^k \) are differentiable functions. \( I_{\alpha}, J_{\alpha}, \) \( \alpha = 0, 1, 2, \ldots, r \) are partitions of the sets \( M = \{1, 2, 3, \ldots, m\} \), \( K = \{1, 2, 3, \ldots, k\} \) respectively. Also \( r = \max\{r_1, r_2\} \) where \( r_1, r_2 \) is the number of partitions of \( M \) and \( K \) respectively and \( J_{\alpha} = \Phi \) or \( I_{\alpha} = \Phi \) for \( \alpha > \min\{r_1, r_2\} \). Here \( y_{l_a} \) denotes the vector consisting of the components \( y_i \) of \( y \) such that \( i \in I_{l_a} \). Similar meanings apply to \( g_{l_a}, z_{j_a} \) and \( y_{l_a} \).

**Theorem 5 (Weak duality).** If for all feasible \( x \) in (PE) and \((u, y, z)\) in (DEG) there is a sublinear functional \( F_{x,u} \) such that \( f + y^T_l g_{l_0} + z^T_j h_{j_0} \) is \( F \)-pseudoconvex and \( y^T_l g_{l_a} + z^T_j h_{j_a}, \alpha = 1, 2, \ldots, r \) is \( F \)-quasiconvex, then Minimum (PE) \( \geq \) Maximum (DEG).

**Proof.** Since \( x \) and \((u, y, z)\) are feasible

\[ y^T_l g_{l_a}(x) + z^T_j h_{j_a}(x) - y^T_l g_{l_a}(u) - z^T_j h_{j_a}(u) \leq 0, \quad \alpha = 1, 2, \ldots, r, \tag{20} \]

and since \( y^T_l g_{l_a} + z^T_j h_{j_a} \) is \( F \)-quasiconvex, \( \alpha = 1, 2, \ldots, r \), we have

\[ F_{x,u} \left[ \nabla \left( y^T_l g_{l_a}(u) + z^T_j h_{j_a}(u) \right) \right] \leq 0, \quad \alpha = 1, 2, \ldots, r, \tag{21} \]

and since \( F_{x,u} \) is sublinear we have

\[ F_{x,u} \left[ \sum_{\alpha=1}^{r} \nabla \left( y^T_l g_{l_a}(u) + z^T_j h_{j_a}(u) \right) \right] \leq \sum_{\alpha=1}^{r} F_{x,u} \left[ \nabla \left( y^T_l g_{l_a}(u) + z^T_j h_{j_a}(u) \right) \right] \leq 0, \tag{22} \]
where (22) follows from (21). Also from the equality constraint of (DEG) i.e. (17) and sublinearity of $F_{x,u}$ we have
\[
F_{x,u} \left[ \nabla \left( f(u) + y'_{i_0} g_{i_0}(u) + z'_{j_0} h_{j_0}(u) \right) \right] 
\geq -F_{x,u} \left[ \nabla \left( y'_{M \setminus I_0} g_{M \setminus I_0}(u) + z'_{K \setminus J_0} h_{K \setminus J_0}(u) \right) \right].
\]
(23)

But $y'_{M \setminus I_0} g_{M \setminus I_0} + z'_{K \setminus J_0} = \sum_{a=1}^{r} (y'_{I_a} g_{I_a} + z'_{J_a} h_{J_a})$. Therefore (22) and (23) yield
\[
F_{x,u} \left[ \nabla \left( f(u) + y'_{i_0} g_{i_0}(u) + z'_{j_0} h_{j_0}(u) \right) \right] \geq 0
\]
(24)

and since $f + y'_{i_0} g_{i_0} + z'_{j_0} h_{j_0}$ is F-pseudoconvex, then from (24) we have
\[
f(x) + y'_{i_0} g_{i_0}(x) + z'_{j_0} h_{j_0}(x) \geq f(u) + y'_{i_0} g_{i_0}(u) + z'_{j_0} h_{j_0}(u)
\]
and since $y'_{i_0} g_{i_0}(x) + z'_{j_0} h_{j_0}(x) \leq 0$ we have
\[
f(x) \geq f(u) + y'_{i_0} g_{i_0}(u) + z'_{j_0} h_{j_0}(u).
\]

**Theorem 6 (Strong duality).** If $x^0$ is a local or global minimum of (PE) at which a constraint qualification is satisfied, then there exists a $(y^0, z^0)$ such that $(x^0, y^0, z^0)$ is feasible for (DEG) and the corresponding values of (PE) and (DEG) are equal. If also there exists a sublinear functional $F_{x,u}$ such that $f + y'_{i_0} g_{i_0} + z'_{j_0} h_{j_0}$ is F-pseudoconvex and $y'_{i_a} g_{i_a} + z'_{j_a} h_{j_a}, \alpha = 1, 2, \ldots, r$ is F-quasiconvex for all feasible $(x, u, y, z)$, then $x^0$ and $(x^0, y^0, z^0)$ are global optimal solutions of (PE) and (DEG) respectively.

**Proof.** Since $x^0$ solves (PE) either locally or globally and a constraint qualification is satisfied; then by the Kuhn-Tucker conditions [3], [4] there exists a $z^0 \in \mathbb{R}^e$ and $y^0 \in \mathbb{R}^m_+$ such that
\[
\nabla f(x^0) + \nabla y^0 g(x^0) + \nabla z^0 h(x^0) = 0,
\]
\[
y^0 g(x^0) = 0, \quad g(x^0) \leq 0 \quad \text{and} \quad y^0 \geq 0.
\]
From $g(x^0) \leq 0$, $y^0 \geq 0$, and $y^0 g(x^0) = 0$ we conclude that $y^0 g_i(x^0) = 0$ for $i = 1, 2, \ldots, m$ and since $h(x^0) = 0$ we must have
\[
y^0 g_i(x^0) + z^0 h_i(x^0) = 0, \quad \alpha = 0, 1, 2, \ldots, r.
\]
Hence $(x^0, y^0, z^0)$ is feasible in (DEG) and the values of (PE) and (DEG) are equal. Now since there exists a sublinear functional $F_{x,u}$ such that $f + y'_{i_0} g_{i_0} + z'_{j_0} h_{j_0}$ is F-pseudoconvex and $y'_{i_a} g_{i_a} + z'_{j_a} h_{j_a}$ is F-quasiconvex for all feasible $(x, u, y, z)$, optimality follows from weak duality.

3. Converse duality

Here we give a strict converse duality of Mangasarian type. The result given here generalizes the results obtained by Weir [8], Gulati and Craven [1] and by Mond and Egudo [6].
First we consider strict converse duality between (P) and (DMW). Later we shall give a strict converse duality between (PE) and (DEG) which is a general converse dual corresponding to Theorem 6 above.

**Theorem 7 (Strict Converse Duality).** Let (P) have an optimal solution at \( x^0 \) at which a constraint qualification is satisfied. Assume that there exists a sublinear functional \( F_{x,u} \) such that \( f \) is \( F \)-pseudoconvex and \( y'g \) is \( F \)-quasiconvex for all feasible \( x \) in (P) and \((u, y)\) in (DMW). If \((\bar{u}, \bar{y})\) is an optimal solution of (DMW) and \( f \) is strictly \( F \)-pseudoconvex at \( \bar{u} \) for all feasible \( x \) in (P), then \( \bar{u} = x^0 \) i.e. \( \bar{u} \) solves (P).

**Proof.** We assume \( x^0 \neq \bar{u} \) and exhibit a contradiction.

Since \( x^0 \) is an optimal solution at which a constraint qualification is satisfied, it follows from Theorem 4 that there exists a \( \bar{y} \) such that \((x^0, \bar{y})\) is an optimal solution for the dual (DMW). Since \((\bar{u}, \bar{y})\) is also optimal for (DMW), it follows that

\[
f(x^0) = f(\bar{u}),
\]

For all feasible \( x \) and \((u, y)\), we have \( y'g(x) - y'g(u) \leq 0 \) and, by \( F \)-quasiconvexity of \( y'g \), we have

\[
F_{x,u}[\nabla y'g(u)] \leq 0.
\]

By (8) and sublinearity of \( F_{x,u} \), we have

\[
F_{x,u}[\nabla f(u)] \geq -F_{x,u}[\nabla y'g(u)].
\]

Now (26) and (27) yield

\[
F_{x,u}[\nabla f(u)] \geq 0.
\]

From (28) and strict \( F \)-pseudoconvexity of \( F_{x,u} \) at \( \bar{u} \) we obtain

\[
F_{x,\bar{u}}[\nabla f(\bar{u})] \geq 0 \Rightarrow f(x) > f(\bar{u}) \text{ for all feasible } x \text{ in (P)}.
\]

And since \( x^0 \) is feasible in (P), we now have \( f(x^0) \geq f(\bar{u}) \) contradicting (25). Hence \( x^0 = \bar{u} \).

**Theorem 8 (Strict Converse Duality).** Let \( x^0 \) be an optimal solution of (PE) at which a constraint qualification is satisfied. Suppose there exists a sublinear functional \( F_{x,u} \) such that \( f + y^i_0 g_{I_0} + z^j_o h_{J_0} \) is \( F \)-pseudoconvex and \( y^i_0 g_{I_0} + z^j_o h_{J_0} \) are \( F \)-quasiconvex for all feasible \( x \) in (P) and \((u, y, z)\) in (DEG). If \((\bar{u}, \bar{y}, \bar{z})\) is an optimal solution of (DEG) and if also \( f + y^i_0 g_{I_0} + z^j_o h_{J_0} \) is strictly \( F \)-pseudoconvex at \( \bar{u} \), then \( \bar{u} = x^0 \) i.e. \( \bar{u} \) solves (PE) and

\[
f(x^0) = f(\bar{u}) + y^i_0 g_{I_0}(\bar{u}) + z^j_o h_{J_0}(\bar{u}).
\]
PROOF. We assume \( x^0 \neq \bar{u} \) and exhibit a contradiction. Since \( x^0 \) is a solution of (PE) at which a constraint qualification is satisfied, it follows from Theorem 6 that there exists \((y^0, z^0)\) such that \((x^0, y^0, z^0)\) solves (DEG). Hence
\[
f(x^0) = f(x^0) + y^0_i g_{I_0}(x^0) + z^0_i h_{J_0}(x^0)
= f(\bar{u}) + y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}).
\] (29)

Now \((\bar{u}, \bar{y}, \bar{z})\) feasible in (DEG) implies
\[
y^0_i g_{I_0}(x^0) + z^0_i h_{J_0}(x^0) - y^0_i g_{I_0}(\bar{u}) - z^0_i h_{J_0}(\bar{u}) \leq 0, \quad \alpha = 1, 2, \ldots, r.
\]
This with \(F\)-quasiconvexity of \( y^0_i g_{I_0} + z^0_i h_{J_0}, \alpha = 1, 2, \ldots, r \) for all feasible \((x, u, y, z)\) yields
\[
F_{x, \bar{u}} \left[ \nabla \left( y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}) \right) \right] \leq 0, \quad \alpha = 1, 2, \ldots, r,
\] (30)

From sublinearity of \(F_{x, \bar{u}}\) we have
\[
F_{x, \bar{u}} \left[ \sum_{\alpha=1}^{r} \nabla \left( y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}) \right) \right] \leq \sum_{\alpha=1}^{r} F_{x, \bar{u}} \left[ \nabla \left( y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}) \right) \right]
\leq 0,
\] (31)

where (31) follows from (30). From equality constraint of (DEG), that is (17), and sublinearity of \(F_{x, \bar{u}}\), we have
\[
F_{x, \bar{u}} \left[ \nabla \left( f(\bar{u}) + y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}) \right) \right] \geq - \sum_{\alpha=1}^{r} F_{x, \bar{u}} \left[ \nabla \left( y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}) \right) \right]
\geq 0,
\] (32)

where (32) follows from (31). Now from (32) and strict \(F\)-pseudoconvexity of \( f + y^0_i g_{I_0} + z^0_i h_{J_0} \) at \( \bar{u} \) we obtain
\[
f(x) + y^0_i g_{I_0}(x) + z^0_i h_{J_0}(x) > f(\bar{u}) + y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u})
\]
for all feasible \(x\) in (PE). From this we obtain
\[
f(x^0) + y^0_i g_{I_0}(x^0) + z^0_i h_{J_0}(x^0) > f(\bar{u}) + y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}).
\]
But \( y^0_i g_{I_0}(x^0) + z^0_i h_{J_0}(x^0) \leq 0 \), hence
\[
f(x^0) > f(\bar{u}) + y^0_i g_{I_0}(\bar{u}) + z^0_i h_{J_0}(\bar{u}),
\]
contradicting (29). So \( x^0 = \bar{u} \).

4. Some special cases

We now consider some special cases of the dual (DEG) and Theorems 5, 6 and 8.

(i) If \( K = \Phi, I_0 = M \) then (PE) becomes (P) and (DEG) becomes (DW) and Theorems 5 and 6 reduce to Theorems 1 and 2 respectively.
(ii) If \( K = \emptyset, I_0 = \emptyset, I_1 = M \) then (PE) becomes (P) and (DEG) becomes (DMW) and Theorems 5, 6 and 8 reduce to Theorems 3, 4 and 7 respectively.

(iii) If \( I_0 = M \) and \( J_0 = K \) then (DEG) becomes

\[
\begin{align*}
\text{Maximize} & \quad f(u) + y'g(u) + z'h(u) \\
\text{subject to} & \quad \nabla f(u) + \nabla y'g(u) + \nabla z'h(u) = 0, \\
& \quad y > 0.
\end{align*}
\]

Duality holds between (PE) and (DE) if there exists a sublinear functional \( F_{x,u} \) such that \( f + y'g + z'h \) is \( F \)-pseudoconvex.

(iv) If \( I_0 = \emptyset, J_0 = \emptyset, I_1 = M, J_1 = K \) then (DEG) becomes

\[
\begin{align*}
\text{Maximize} & \quad f(u) \\
\text{subject to} & \quad \nabla f(u) + \nabla y'g(u) + \nabla z'h(u) = 0, \\
& \quad y'g(u) + z'h(u) \geq 0, \\
& \quad y > 0.
\end{align*}
\]

If there exists a sublinear functional \( F_{x,u} \) such that \( f \) is \( F \)-pseudoconvex and \( y'g + z'h \) is \( F \)-quasiconvex for all feasible \( (x, u, y, z) \) then from Theorems 5, 6 and 8, (DEM) is dual to (PE).

(v) If \( I_0 = \emptyset, J_0 = K, I_1 = M \) then (DEG) becomes

\[
\begin{align*}
\text{Maximize} & \quad f(u) + z'h(u) \\
\text{subject to} & \quad \nabla f(u) + \nabla y'g(u) + \nabla z'h(u) = 0, \\
& \quad y'g(u) \geq 0, \\
& \quad y > 0.
\end{align*}
\]

If there exists a sublinear functional \( F_{x,u} \) such that \( f + z'h \) is \( F \)-pseudoconvex and \( y'g \) is \( F \)-quasiconvex, then from Theorems 5, 6 and 8 (DMT) is dual to (PE).

(vi) If \( J_0 = \emptyset, I_0 = M, J_1 = K \) then (DEG) becomes

\[
\begin{align*}
\text{Maximize} & \quad f(u) + y'g(u) \\
\text{subject to} & \quad \nabla f(u) + \nabla y'g(u) + \nabla z'h(u) = 0, \\
& \quad z'h(u) \geq 0, \\
& \quad y > 0.
\end{align*}
\]

(DME) is dual to (PE) if there exists a sublinear functional \( F_{x,u} \) such that \( f + y'g \) is \( F \)-pseudoconvex and \( z'h \) is \( F \)-quasiconvex.

(vii) If \( K = \emptyset, I_0 = \emptyset, I_\alpha = \{\alpha\}, \alpha = 1, 2, \ldots, m \) then (PE) becomes (P) and (DEG) becomes

\[
\begin{align*}
\text{Maximize} & \quad f(u) \\
\text{subject to} & \quad \nabla f(u) + \nabla y'g(u) = 0, \\
& \quad y, z > 0, \\
& \quad (i = 1, 2, \ldots, m), \\
& \quad y > 0.
\end{align*}
\]
If there exists a sublinear functional $F_{x,u}$ such that $f$ is $F$-pseudoconvex and $g$ is $F$-quasiconvex then from Theorems 5, 6 and 8 (DG) is dual to (P).

(viii) In (ii) $y'g$ is required to be $F$-quasiconvex while in (vii) only $g$ is required to be $F$-quasiconvex. It may be possible to combine some but not all components of $g$ into a single $F$-quasiconvex function while the other components are individually but not collectively $F$-quasiconvex. In this case we can find a dual between (DMW) and (DG) as follows. Put $K = \Phi$, $I_0 = \Phi$ and $Q \subset M$ then (DEG) becomes

Maximize $f(u)$
subject to $\nabla f(u) + \nabla y'g(u) = 0$,

$(DM)$

$$\sum_{i \in Q} y_i g_i(u) \geq 0,$$
$$y_j g_j(u) \geq 0, \quad j \in M \setminus Q,$$
$$y \geq 0.$$

If there exists a sublinear functional $F_{x,u}$ such that $f$ is $F$-pseudoconvex and $\sum_{i \in Q} y_i g_i$ is $F$-quasiconvex and $g_j, \ j \in M \setminus Q$ are $F$-quasiconvex, then from Theorems 5, 6 and 8, (DM) is dual to (P).

(ix) If only part of the Lagrangian is pseudoconvex, then it is possible to obtain a dual between the Wolfe dual and (DG). For example if $K = \Phi$, and $I_0, Q \subset M$, $I_0 \cap Q = \Phi$, then (DEG) becomes

Maximize $f(u) + y'_0 g_{I_0}(u)$
subject to $\nabla f(u) + \nabla y'g(u) = 0$,

$(DWG)$

$$\sum_{i \in Q} y_i g_i \geq 0,$$
$$y'_j g'_j(u) \geq 0 \quad (j \in M \setminus (Q \cup I_0)),$$
$$y \geq 0.$$

If there exists a sublinear functional $F_{x,u}$ such that $f + y'_0 g_{I_0}$ is $F$-pseudoconvex and $\sum_{i \in Q} y_i g_i$ is $F$-quasiconvex and $g_j, \ j \in M \setminus (Q \cup I_0)$ is $F$-quasiconvex for all feasible $(x, u, y)$ then from Theorems 5, 6 and 8, (DWG) is dual to (P).
