Abstract

The present study was carried out to evaluate the effects of virgin coconut oil (VCO) compared with copra oil, olive oil and sunflower-seed oil on the synthesis and oxidation of fatty acids and the molecular regulation of fatty acid metabolism in normal rats. Male Sprague–Dawley rats were fed the test oils at 8% for 45 d along with a synthetic diet. Dietary supplementation of VCO decreased tissue lipid levels and reduced the activity of the enzymes involved in lipogenesis, namely acyl CoA carboxylase and fatty acid synthase (FAS) (P<0·05). Moreover, VCO significantly (P<0·05) reduced the de novo synthesis of fatty acids by down-regulating the mRNA expression of FAS and its transcription factor, sterol regulatory element-binding protein-1c, compared with the other oils. VCO significantly (P<0·05) increased the mitochondrial and peroxisomal β-oxidation of fatty acids, which was evident from the increased activities of carnitine palmitoyl transferase I, acyl CoA oxidase and the enzymes involved in mitochondrial β-oxidation; this was accomplished by up-regulating the mRNA expression of PPARα and its target genes involved in fatty acid oxidation. In conclusion, the present results confirmed that supplementation of VCO has beneficial effects on lipid parameters by reducing lipogenesis and enhancing the rate of fatty acid catabolism; this effect was mediated at least in part via PPARα-dependent pathways. Thus, dietary VCO reduces the risk for CHD by beneficially modulating the synthesis and degradation of fatty acids.

Key words: Virgin coconut oil; Fatty acid synthesis; β-Oxidation; PPARα

CVD, which is often associated with hyperlipidaemia, has become the major cause of death in many countries (1,2). Elevated peripheral NEFA and de novo lipogenesis predominantly contribute to the accumulation of lipids in the liver (3), which is mostly controlled by the intake of different dietary fats through changes in hepatic enzyme activities related to the metabolism of fatty acids (4). In general, fat accumulation in the body may be considered as the net result of the balance among dietary absorbed fat, endogenous synthesis of fat and the catabolism of fat via β-oxidation.

It has been shown that different fatty acids exert different effects on the transcription of specific genes involved in hepatic lipid metabolism (5–6). Transcriptional regulation of fatty acid metabolism is considered to be the major regulatory mechanism controlling lipid homeostasis, which is executed by a variety of transcription factors (7). Sterol response element-binding protein-1c (SREBP-1c; 68 kDa) is a transcription factor known to be the major regulator of lipogenic enzymes (8) and reduced expression of SREBP-1c is a primary mechanism by which dietary fatty acids reduce hepatic lipogenesis. In contrast with the numerous factors involved in fatty acid synthesis and storage, the transcriptional regulation of fatty acid oxidation has long been dominated by PPARα, which is a nuclear receptor activated by natural ligands such as fatty acids and stimulates β-oxidation of SFA in mitochondria and PUFA in the peroxisomes (9). Some of the enzymes of these two systems are highly inducible by natural and synthetic ligands of PPARα (10,11).

Nutritional status, particularly the dietary fatty acid pattern of the individual, plays a key role in regulating fatty acid metabolism (12). The diversity in fatty acid structure resulting from differences in chain length, degree of unsaturation, position and stereoisomeric configuration of the double bonds may affect the rate of fatty acid oxidation. Although the usual dietary fats composed of mainly long-chain fatty acids are known to be powerful inhibitors of lipogenesis in the liver and adipose tissue (13), paradoxically they produce obesity (14).

Coconut oil extracted from dried copra is the characteristic cooking medium in most of the culinary preparations in all coconut-producing countries. Nowadays, virgin coconut oil (VCO) extracted from fresh coconut kernel by wet processing is

Abbreviations: ACC, acetyl CoA carboxylase; ACIDH, acyl CoA dehydrogenase; ACO, acyl CoA oxidase; CO, copra oil; CPT I, carnitine palmitoyl transferase I; FAS, fatty acid synthase; MSE, mannitol–sucrose–EDTA; OO, olive oil; SFQ, sunflower-seed oil; SIRT1, sirtuin 1; SREBP-1c, sterol regulatory element-binding protein-1c; VCO, virgin coconut oil.

* Corresponding author: Professor T. Rajamohan, fax +91 471 2308078, email trmohanbio@gmail.com
becoming very valuable because of its biological properties. Individual fatty acid analysis of the two types of coconut oil has revealed the presence of higher amounts of short- and medium-chain TAG, mainly lauric acid\(^{(15)}\). The major advantage of medium-chain fatty acids in coconut oil is that they are more rapidly oxidised by both mitochondrial and peroxisomal pathways compared with MUFA and PUFA\(^{(16)}\). Moreover, VCO extraction by wet processing retains higher amounts of unsaponifiable components such as polyphenols, tocopherols and phytosterols\(^{(17,18)}\). Previous studies have reported that VCO possesses significant hypolipidemic, antioxidant and anti-thrombotic effects compared with copra oil (CO)\(^{(15,17,19)}\). In addition, our recent reports have revealed that VCO has beneficial effects on regulating hepatic lipid metabolism \textit{in vivo} \(^{(20)}\).

In view of these findings, the present study was carried out to evaluate the effects of VCO compared with CO, oleate-rich olive oil (OO) and linoleate-rich sunflower-seed oil (SFO) on the synthesis and oxidation of fatty acids and its effect on the transcriptional regulation of fatty acid metabolism in rats.

**Materials and methods**

**Chemicals**

Acetyl CoA, malonyl CoA, NAD phosphate, L-carnitine, ATP, TRI reagent and primers used for RT-PCR were obtained from Sigma Chemicals. cDNA synthesis and PCR reactions were performed using a kit purchased from Fermentas, Thermo Fisher Scientific Inc. and all other chemicals used were of the highest analytical grade.

**Extraction of virgin coconut oil and copra oil**

The solid endosperm of mature coconut (West coast tall variety) was crushed, made into viscous slurry and squeezed through cheesecloth to obtain coconut milk, which was refrigerated for 48 h, then subjected to mild heating (50°C) in a thermostat oven. The obtained VCO filtered through cheesecloth was used for the present study \(^{(17)}\). CO was extracted from coconut meat, which was dried in sunlight continuously for 4 d to remove moisture and the resulting copra was pressed in a mill to obtain CO\(^{(17)}\).

**Olive oil and sunflower-seed oil**

OO (Pietro Coricelli brand) and SFO (Sun drop brand) were purchased from a local market.

**Animals**

Male Sprague–Dawley rats (100–120 g) bred in our departmental animal house were used for the study. Animals were individually housed under hygienic conditions in polypropylene cages in a room maintained at an ambient temperature of 25 ± 1°C with a 12 h light–12 h dark cycle. The entire protocol was approved by the Animal Ethics Committee, University of Kerala (IAEC-KU-8/09-10-BC-TR \(^{(17)}\)) and the animals were handled using welfare guidelines for laboratory animals.

**Experimental design**

A total of twenty-four rats were divided into four groups. The experimental design was as follows: group I rats were given 8% CO; group II rats were given 8% VCO; group III rats were given 8% OO; and group IV rats were given 8% SFO. Each rat was given 12 g synthetic diet containing 8% dietary oils daily for 45 d as described previously (Table 1)\(^{(17,21)}\). The fatty acid compositions of test oils were estimated by GC-MS and reported previously (Table 2)\(^{(22)}\). Food intakes of rats were noted daily and the body weight was determined weekly. After 45 d, animals were fasted overnight and killed by sodium pentathione injection. Blood and tissues were collected for various estimations.

**Change in body weight**

The body weight of each animal was noted before starting the feeding experiment and also on the experimental day. Change in body weight was calculated as follows:

\[
\text{Change in body weight (g) = final weight} \quad \text{− initial weight}. \\
\]

**Lipid analysis**

Total lipids from serum and tissues were extracted using chloroform–methanol (2:1, v/v) as described previously\(^{(23)}\). Tissue (500 mg) or serum (0.5 ml) was homogenised with chloroform–methanol (2:1, v/v), filtered and washed with chloroform–methanol at least three times. Calcium chloride (0.02%) was added to the mixture (20% of the total volume of the extract), mixed vigorously and allowed to stand for a few minutes. The upper layer was washed three times with 5 ml chloroform–methanol–calcium chloride (3:48:48, by vol.). The washed upper layer was evaporated to dryness and the residue was redisolved in a known volume of chloroform. From this, samples were used for lipid analysis. Total cholesterol was estimated as described by Carr & Drekter\(^{(24)}\). TAG were estimated by the method of Van Handel & Zilversmit\(^{(25)}\).

Estimation of phospholipids

Phospholipids were estimated by the method of Zilversmit & Davis (28). A sample of the extract was pipetted out into Kjeldahl flask and evaporated to dryness. Then 1 ml of H₂SO₄ (2.5 M) was added and the sample was digested until it became light brown. It was cooled to room temperature and two drops of HNO₃ (2 M) were added and the sample digested again until it became colourless. The Kjeldahl flask was cooled, 1 ml water was added and heated in a boiling water-bath for 5 min. Then 1 ml of ammonium molybdate (2.5%) and 0.1 ml of 1-amino 2-naphthol 4-sulfonic acid (ANSA) reagent were added and heated in a boiling water-bath for 5 min. Then 1 ml of water was added and heated again until it became brown. The Kjeldahl flask was cooled, 1 ml water was added and heated in a boiling water-bath for 5 min. The supernatant fraction was decanted and the pellets were discarded. The mitochondrial pellet was then re-suspended in 40 ml of MSE medium, and the volume made up to 10 ml with distilled water. After 10 min, absorbance was measured at 660 nm using a Shimadzu 1240 spectrophotometer.

Isolation of mitochondria and peroxisomes

Mitochondria were separated from the heart according to Tyler & Gomez (29). Rat heart tissue was washed in cold MSE medium (0.225 M-mannitol, 0.075 M-sucrose and 0.05 mM-EDTA, pH 7.4) and finely chopped. The chopped heart tissue was washed and finely chopped. The chopped heart tissue was washed in cold MSE medium and 0.05 ml of un-neutralised Tris buffer (1 M) and finely chopped. The chopped heart tissue was washed with distilled water. After 10 min, absorbance was measured at 660 nm using a Shimadzu 1240 spectrophotometer.

Mitochondrial and peroxisomal β-oxidation

Mitochondrial β-oxidation (30) and the activities of carnitine palmitoyl transferase I (CPT I) (31), acyl CoA dehydrogenase (ACDH) (32), enoyl CoA hydratase (33), β-hydroxy acyl CoA dehydrogenase (34) and 3-ketoacyl CoA thiolase (35) were determined in isolated mitochondria. The peroxisomal fraction was used for determining the activity of acyl CoA oxidase (ACO) (36).

De novo fatty acid synthesis

The enzymes involved in de novo fatty acid synthesis, namely acetyl CoA carboxylase (ACC) (37) and fatty acid synthase (FAS) (38), were assayed in liver using a Shimadzu 1240 spectrophotometer.

Isolation of total genomic RNA

Total genomic RNA was isolated from the heart using TRI reagent (Sigma Aldrich) by the method described by Chomczynski & Mackey (39).

cDNA synthesis and RT-PCR

cDNA synthesis and PCR reactions were performed in a thermocycler (Eppendorf AG) according to the manufacturer’s instructions using a kit purchased from Fermentas. The primers used were: FAS (forward) 5'-AGG TGC TAG AGG CCC TGC TA-3' and (reverse) 5'-GTG CAC AGA CAC CTT CCC AT-3'; SREBP-1c (forward) 5'-GGAGCCATGGATTGCACATT-3' and (reverse) 5'-AGGAAGGCTTCCAGAGAGGA-3'; PPARα (forward) 5'-GGCCTTGACCT-3' and (reverse) 5'-CTT TCT TGC TGG ACT TGT CAA ACC A-3'; ACO (forward) 5'-CTT CTC TGT CCG CTT CGT CCA ACC A-3' and (reverse) 5'-GCC GTT TCA CCG CCT CGT A-3'; PPARG (forward) 5'-CAATGC-3' and (reverse) 5'-GCCCTGACCTT-GTTCATGT-3'; glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (forward) 5'-CTT CTC TAT GCC TCA ACT AC-3' and (reverse) 5'-GGGA AGG CCA TGC CAG TGA GC-3'.

The PCR products were electrophoresed on 1.5% agarose gel and visualised by staining with ethidium bromide. The gels were subjected to densitometric scanning (Bio-Rad Gel Doc) to determine the optical density of each and then normalised against an internal control (GAPDH) using Quantity One imaging software (Bio-Rad Laboratories).

Statistical analysis
Data are presented as means with their standard errors. Statistical analysis was performed by one-way ANOVA followed by Duncan’s multiple-range tests using the SPSS/PC (version 17.0; SPSS) software package program. P values < 0.05 were considered significant.

Results
Dietary intake and change in body weight

There was no significant difference in diet consumption and change in body weight among the experimental groups (Table 3).

Effect on serum and liver lipids

Table 4 summarises the levels of lipids in the serum and liver of rats fed the different test oils. The concentration of total cholesterol (1.87 mmol/l serum; 128.57 mg/100 g liver), TAG (0.11 mmol/l serum; 154.78 mg/100 g liver) and phospholipids (1.01 mmol/l serum; 1789.66 mg/100 g liver) were decreased significantly (P < 0.05) in VCO-fed rats compared with those fed CO, OO and SFO. Supplementation of VCO decreased the cholesterol levels (22.72% decrease in serum and 51.25% decrease in liver) compared with rats fed CO. Similarly, there was a 28.62% decrease in serum cholesterol levels and a 54.05% decrease in hepatic cholesterol levels in VCO-fed rats compared with rats fed OO. Decreased levels of TAG (15.38% decrease in serum and 15.13% decrease in liver) and phospholipids (40.93% decrease in serum and 18.34% decrease in liver) were observed in VCO-fed rats compared with rats fed CO. A significant increase in TAG and phospholipids levels was observed in OO- (26.66% increase in serum TAG and 49.50% increase in serum phospholipids) and SFO- (21.42% increase in serum TAG and 41.28% increase in serum phospholipids) compared with VCO-fed rats.

Effect on synthesis and oxidation of fatty acids

Activities of enzymes involved in de novo fatty acid synthesis were assayed in the liver cytosolic fraction from rats fed the different test oils. Reduced rates of fatty acid synthesis were evident from the decreased activities of enzymes involved in fatty acid synthesis, namely ACC (9.38 U/mg protein) and FAS (18.78 U/mg protein), in VCO-fed rats compared with rats fed CO, OO and SFO. Significant decreases in the activities of CPT I and ACO were observed in rats fed CO (13.07% decrease in CPT I and 18.86% decrease in ACO), OO (29.08% decrease in CPT I and 30.78% decrease in ACO) and SFO (21.42% decrease in CPT I and 27.78% decrease in ACO) compared with VCO-fed rats (Fig. 1). However, the rates of mitochondrial β-oxidation (0.305 U/mg protein) and peroxisomal β-oxidation (4.53 U/mg protein) were significantly (P < 0.05) increased in rats fed VCO compared with the other oil-fed rats (Table 5). Significant decreases in the activities of CPT I and ACO were observed in rats fed CO (13.07% decrease in CPT I and 18.86% decrease in ACO), OO (29.08% decrease in CPT I and 30.78% decrease in ACO) and SFO (18.30% decrease in CPT I and 27.78% decrease in ACO) compared with VCO-fed rats (Fig. 2). The enzymes involved in mitochondrial β-oxidation, namely ACDH (0.768 U/mg protein), enoyl CoA hydratase (0.364 U/mg protein), β-hydroxy acyl CoA dehydrogenase (0.620 U/mg protein) and 3-ketoacyl CoA thiolase (0.224 U/mg protein), were also increased significantly (P < 0.05) in rats fed VCO compared with the other oil-fed groups (Table 6). Significant decreases in the activities of ACDH (67.83%), ECDH (47.03%), β-hydroxy acyl CoA dehydrogenase (65.64%) and 3-ketoacyl CoA thiolase (39.73%) were observed in OO-fed rats compared with VCO-fed rats (Table 6).

Effect on transcriptional regulation of fatty acid metabolism

There was a down-regulation in the mRNA expression of FAS (the multi-enzyme complex involved in de novo fatty acid synthesis) and its transcription factor SREBP-1c in VCO-fed rats compared with the other oil-fed groups (Fig. 3). On the other hand, the mRNA expression of PPARα and its target genes involved in fatty acid oxidation, namely CPT I and ACO, were up-regulated in VCO-fed rats compared with CO-, OO- and SFO-fed rats (Fig. 4).

Discussion

In the present study we compared the effects of VCO with CO, OO and SFO on the synthesis and oxidation of fatty acids and its effect on the molecular regulation of fatty acid metabolism in rats. There was no significant difference in food intake or change in body weight among the experimental groups. Supplementation of VCO decreased the concentration of lipids (cholesterol, TAG and phospholipids) in serum and liver when compared with CO-, OO- and SFO-fed rats. However, OO-fed rats showed an increased level of hepatic lipid accumulation compared with rats fed the other oils, which may be due to an increased lipogenesis and decreased catabolism of fats in OO-fed rats. There are reports that dietary fat influences the occurrences and prognosis of CHD, which is partially mediated by its effect on plasma lipids.

Fatty acid biosynthesis in mammalian cells can be regulated in different ways. On a long-term basis, it is controlled by changes in the rate of synthesis of lipogenic enzymes. As shown in Fig. 1, activities of enzymes involved in the de novo synthesis of fatty acids, namely ACC and FAS, were found to be decreased in VCO-fed rats compared with the other oil-fed rats. ACC catalyses the carboxylation of acetyl-CoA to produce malonyl-CoA for the biosynthesis of fatty acids. There are reports of increased lipogenesis in OO-fed animals. On the other hand, medium-chain fatty acid oxidation (the multi-enzyme complex involved in de novo synthesis of fatty acids) is partially mediated by its effect on plasma lipids.

Group I, 8% copra oil-fed rats; group II, 8% virgin coconut oil-fed rats; group III, 8% olive oil-fed rats; group IV, 8% sunflower-seed oil-fed rats.

* Mean value was significantly different from that of group I (P<0.05).
† Mean value was significantly different from that of group II (P<0.05).
The OO-enriched diet showed a maximum decrease in the ACO in VCO-fed rats compared with the other oil-fed rats. There are reports that long-chain fatty acids (>C20) require peroxisomal β-oxidation to shorten the chain length for further completion of oxidation in mitochondria. Thus both the substrate specificities and alterations in the activities of the β-oxidation enzymes may account for the decreased lipogenesis and lipid accumulation compared with other oils. There are reports that polyphenols can inhibit hepatic lipogenesis, promote hepatic lipid clearance and decrease serum and hepatic lipid accumulation. Increased amounts of polyphenols present in VCO may decrease the lipid levels (cholesterol, TAG and phospholipids) compared with other oils. Some of the beneficial metabolic actions of polyphenols are mediated by their ability to activate sirtuin 1 (SIRT1) or AMP-activated protein kinase (AMPK). SIRT1 is a NAD-dependent class III histone deacetylase. Polyphenols stimulate hepatic SIRT1 activity and reduce lipid accumulation; however, the underlying mechanisms remain unclear. There are reports that the polyphenols substantially prevent the phosphorylation of AMPK and its downstream element-binding protein-1c (SREBP-1c) in copra oil-fed rats; group III, 8 % olive oil-fed rats; group IV, 8 % sunflower-seed oil-fed rats.

ACDH, acyl CoA dehydrogenase; ECHD, enoyl CoA hydratase; HOAD, β-hydroxy acyl CoA dehydrogenase; KAT, 3-ketoacyl CoA thiolase; group I, 8 % copra oil-fed rats; group II, 8 % virgin coconut oil-fed rats; group III, 8 % olive oil-fed rats; group IV, 8 % sunflower-seed oil-fed rats.

* Mean value was significantly different from that of group I (P<0.05).
† Mean value was significantly different from that of group II (P<0.05).

Coconut oil intake and fatty acid metabolism

Hydrate (0.983 µg/100 g oil) and syringic acid (2.51 mg/100 g oil) compared with CO, OO and SFO; these observations are consistent with other studies. In addition, the non-saponifiable fraction of VCO contains appreciably higher amounts of antioxidants, namely vitamin E (33.12 µg/100 g oil) and β-carotene (196 µg/100 g oil). Increased amounts of these non-saponifiable components present in VCO may partly be responsible for the decreased lipogenesis and lipid accumulation compared with other oils. Increased amounts of these bioactive non-saponifiable components may partly be responsible for the decreased lipogenesis and lipid accumulation compared with other oils.

There are reports that polyphenols can inhibit hepatic lipogenesis, promote hepatic lipid clearance and decrease serum and hepatic lipid accumulation. Increased amounts of polyphenols present in VCO may decrease the lipid levels (cholesterol, TAG and phospholipids) compared with other oils. Some of the beneficial metabolic actions of polyphenols are mediated by their ability to activate sirtuin 1 (SIRT1) or AMP-activated protein kinase (AMPK). SIRT1 is a NAD-dependent class III histone deacetylase. Polyphenols stimulate hepatic SIRT1 activity and reduce lipid accumulation; however, the underlying mechanisms remain unclear. There are reports that the polyphenols substantially prevent the phosphorylation of AMPK and its downstream target, ACC, elevation in the expression of FAS and lipid accumulation in human HepG2 hepatocytes.

Furthermore, increased rates of mitochondrial and peroxisomal β-oxidation were observed in VCO-fed rats, which was evident from the increased activity of CPT I and ACO in VCO-fed rats compared with the other oil-fed rats. There are reports that long-chain fatty acids (>C20) require peroxisomal β-oxidation to shorten the chain length for further completion of oxidation in mitochondria. Thus both the substrate specificities and alterations in the activities of the β-oxidation enzymes may account for the decreased lipogenesis and lipid accumulation compared with other oils.

In addition, an increased rate of peroxisomal β-oxidation was observed in VCO-fed rats, which was evident from the increased activity of ACO in peroxisomes compared with other oil-fed rats. There are reports that long-chain fatty acids (>C20) require peroxisomal β-oxidation to shorten the chain length for further completion of oxidation in mitochondria. Thus both the substrate specificities and alterations in the activities of the β-oxidation enzymes may account for the decreased lipogenesis and lipid accumulation compared with other oils.

Fig. 3. mRNA expression of fatty acid synthase (FAS) and sterol regulatory element-binding protein-1c (SREBP-1c) in copra oil- (CO; ), virgin coconut oil- (VCO; ), olive oil- (OO; ) and sunflower-seed oil (SFO; ; )-fed rats. Values are means of six rats per group, with their standard errors represented by vertical bars. * Mean value was significantly different from that of group I (P<0.05). † Mean value was significantly different from that of group II (P<0.05). GAPDH, glyceraldehyde-3-phosphate dehydrogenase.
amounts of polyphenols in VCO may beneficially regulate fatty acid oxidation. The present study for the first time has evidence that dietary VCO increases the activities of both mitochondrial and peroxisomal enzymes involved in the fatty acid oxidation pathway.

The role of transcriptional regulation of fatty acid metabolism has been studied extensively. Reports indicate that dietary fatty acids suppress hepatic lipogenesis by reducing the transcription of genes coding for the participating enzymes\(^{(59,60)}\). Several lines of evidence have shown that down-regulation of SREBP-1c is a primary mechanism by which dietary fatty acids reduce hepatic lipogenesis. SREBP-1c stimulates the transcription of the enzymes that participate in the synthesis of fatty acids and TAG\(^{(38)}\); there was a down-regulation in the hepatic mRNA expression of PPAR\(\text{\textit{x}}\) and sunflower-seed oil (SFO; \(\square\))-fed rats. Values are means of six rats per group, with their standard errors represented as vertical bars. * Mean value was significantly different from that of group I \((P<0.05)\). † Mean value was significantly different from that of group II \((P<0.05)\). GAPDH, glyceroldehyde-3-phosphate dehydrogenase.

![Fig. 4. mRNA expression of PPAR\(\text{\textit{x}}\) and its target genes carnitine palmitoyl transferase I (CPT I) and acyl CoA oxidase (ACO) involved in fatty acid oxidation in copra oil- (CO; \(\square\)), virgin coconut oil- (VCO; \(\square\)), olive oil- (OO; \(\square\)) and sunflower-seed oil (SFO; \(\square\))-fed rats.](https://www.cambridge.org/core/journals/british-journal-of-nutrition/article/mrna-expression-of-pparalpha-and-its-target-genes-carnitine-palmitoyl-transferase-I-cpt-i-and-acetyl-coa-oxidase-aco-involved-in-fatty-acid-oxidation-in-copra-oil-co-square-virgin-coconut-oil-vco-square-olive-oil-oo-square-and)

that polyphenols increase SIRT1 deacetylase activity\(^{(54)}\), deacetylation of SREBP-1c by SIRT1 inhibits SREBP-1c activity by decreasing its stability and its association with its lipogenic target gene promoters\(^{(63,65)}\).

Moreover, both mitochondrial and peroxisomal \(\beta\)-oxidation systems are under the transcriptional regulation of PPAR\(\text{\textit{x}}\), which is the nuclear receptor activated by natural ligands such as fatty acids\(^{(30)}\). There are reports that medium-chain fatty acids are the natural PPAR ligands\(^{(66)}\) and supplementation of coconut oil up-regulates the mRNA expression of PPAR\(\text{\textit{x}}\)\(^{(67)}\). Moreover, polyphenols are reported to be the natural PPAR\(\text{\textit{x}}\) activators\(^{(49,68)}\). PPAR\(\text{\textit{x}}\) activation up-regulates fatty acid oxidation-related genes such as ACO, CPT I, etc.,\(^{(69)}\) and suppresses postprandial lipidaemia and lipid accumulation through the enhancement of fatty acid oxidation\(^{(70)}\). An up-regulation in the mRNA expression of PPAR\(\text{\textit{x}}\) and its target genes involved in fatty acid oxidation was observed in VCO-fed rats compared with the other oil-fed rats; these results were correlated with the increased activities of enzymes involved in mitochondrial and peroxisomal \(\beta\)-oxidation in VCO-fed rats. Thus, from the present results it is clear that supplementation of VCO regulates fatty acid oxidation partly via PPAR\(\text{\textit{x}}\)-dependent pathways.

In conclusion, dietary VCO beneficially modulates lipid levels and fatty acid metabolism by transcriptional regulation of the enzymes involved in the synthesis and oxidation of fatty acids.
